spasm or contraction of the peripheral vessels, while others think the renal change is only a part of a general vascular inflammation, and that endarteritis is present throughout the system. This gives rise to an obstruction, and the heart hypertrophies to overcome the difficulty. The spastic state of the vessels certainly presents, from whatsoever cause, creates high arterial tension, common to all forms of nephritis, and a classical symptom of chronic interstitial nephritis. By examining, daily, the pulse of patients in whom acute Bright's disease may arise, especially in scarlatina patients, we can detect this high arterial tension, and ascertain when renal trouble is beginning. Some authorities believe the renal disease is not a local inflammation, but a part of the general disease, arguing from the fact that the high tension is present before the albumin is found in the urine. Of course, then, our attention is directed at once to a study of the circulation in a case of nephritis. There is, in this patient, no organic heart disease, and, let me state just here, no affection of the blood, no leucocythemia or malaria; and so we decide that this is a case of general anasarca due to the presence of a subacute catarrhal nephritis. There is, however, some increase in the size of the heart, and an examination of the pulse shows a high arterial pressure. The wave as shown by the sphygmograph is sustained, the tracing is broadened at the top, indicating a persistency of the wave. The artery is hard, and the wave persists under the finger very perceptibly. The presence of high arterial tension is further shown by the marked accentuation of the second aortic sound, in its usual location.

The patient complained of headache. This is sometimes a very prominent feature in acute nephritis and is almost always uremic in nature. Whether it is due to irritation of the nerve centres or meninges by blood loaded with morbid material or to alteration in the tension of the cerebral vessels, I cannot say. I am inclined to think the latter. There is also present a marked inflammation of the vessels in the eye-ground, as shown by a direct examination of the eye. There is here present the so-called retinitis albuminurica—an unfortunate condition; because when hemorrhages occur they are very slowly absorbed. In all cases of altered vision, dimness of vision, sudden blindness, hemiopia and diplopia, examine the urine; for often the condition is due to nephritis, either catarrhal or more likely the interstitial form. This is frequently encountered in pregnant women.

The treatment here is important. Some cases of nephritis will not get well in spite of treatment. The acute form usually recovers under rest, liquid food, the drawing of blood from the kidneys by cups to the loins, and by hot applications to relieve the internal congestion. If the case is a grave one, you may use some general depletion as well. Purgation may be resorted to to empty the vessels and to relieve the pressure on the kidneys. The patient must be kept warm, and hot-air baths—the best because the safest diaphoretic—should be employed. Pilocarpine is debilitating, and therefore not safe. Rest and warmth alone will often suffice. The diet should be skim-milk, buttermilk or whey. Digitalis and salts of potassium may be used after the first ten days. The best purgative to use is cream of tartar in lemonade. If not sufficient, it may be replaced by compound jalap powder or elaterium.

In this patient we have the low-grade passive inflammation with degeneration of the inflammatory products. In him we may use slightly stimulating diuretics. Digitalis has been used with hot-air baths, and pilocarpine has been given, with relief, but not sufficient. The dropsy persists, together with the headache and dimness of vision. He has also had constant delirium, worse at night, with persistent delusions, almost as much so as in insane patients. In other words, in this patient we have the classical cerebral symptoms of uremia coupled with those of catarrhal nephritis. We were not satisfied with digitalis, so we placed him on sparleine and caffeine for the head symptoms, twelve to sixteen grains of the latter in twenty-four hours. The grave symptoms of uremia have disappeared; the dropsy is lessened; and the patient is gradually passing into a condition of comfort. His pulse was weak, and on this account stimulants were given, namely, compound spirits of juniper. As the case progresses it will be wise to give a more decided stimulant, to act more especially on the renal epithelium, such as the terebinthinates, minute doses of cantharides, or sandal-wood. Anemia is present, as usual in all cases of nephritis, and it will be necessary to give preparations of iron or minute doses of arsenic or bichloride of mercury.

COMMUNICATIONS.

DRAINAGE IN ABDOMINAL SURGERY.[1]

BY GEO. ERETY SHOEMAKER, A. M., M. D.,

ATTENDING GYNECOLOGIST TO ST. CLEMENT'S HOSPITAL, OUT-PATIENT SURGEON TO UNIVERSITY AND PRESBYTERIAN HOSPITALS, PHILADELPHIA.

The subject of drainage in abdominal surgery is not new, but a wide difference in practice makes it worth further discussion. The object of this paper is to state the indications for drainage, to describe its proper method, to enter a plea for its more frequent use, and to draw out the views and experience of those present who are interested in the matter. If an ideal operation could in every instance be done, the subject of drainage would have but little importance; but practical methods and not ideal ones must be adopted. The great utility of the drainage-tube is in cases of hemorrhage or of sepsis following abdominal section. When bleeding has been apparently controlled by sponge pressure or by pressure forceps, there must always remain some element of doubt as to what amount of secondary hemorrhage will occur after the patient has reacted from shock, or by reason of the dislodgment of minute clots from subsequent movement of the parts. The ability of the peritoneum to absorb even a large amount of serous exudation or blood cannot be denied; and could the absolute asepsis of this quantity of exudate be assured, Nature would undoubtedly do the work of the drainage-tube in almost all instances. Schede's method of healing surface wounds by the organization of blood clot, and that recently-advocated "dry method" of healing such wounds without drainage, might be used in an argument against abdominal drainage; but they depend for their success upon absolute asepsis.

Perfect surgical cleanliness is undoubtedly the aim of every abdominal operator; but most human beings, including assistants, are fallible. Which of us has succeeded perfectly every time? It is noteworthy too that some of the warmest advocates of drainage are at the same time most rigid in their aseptic methods. The fact remains, that after all skill is used some chances must be taken. Does or does not the drainage-tube in all but the simple cases lessen these chances? For example, in the operations on small tumors deep in the pelvis and in pyosalpinx cases, much of the work must be done by the sense of touch alone, and it is impossible to see the field of operation. Time after time it has occurred to men of the greatest skill to cause a small bowel perforation which it was impossible to detect by the eye; or a small amount of infected material has been extruded in a tedious enucleation. If such a case be not drained the surgeon does not rely on his skill for the recovery of the patient, but on the chances that no harm will follow. Again, the amount of secondary oozing, while it may be possible to gauge it in most cases, will in others, for some reason, be unaccountably great. In the writings of all operators of experience one finds reference to fatal cases in which the one regret was that the drainage-tube had not been used. Not to cite wearisome instances the following language of Bantock, *British Medical Journal*, January 22, 1881, may be quoted: "In my earlier cases I did not resort to the drainage-tube as often as I did in my later, and it was not till I had lost a patient under circumstances in which I would now consider it indispensable that I saw the importance and value of the instrument." Again, Thomas Keith, Contributions to the Surgical Treatment of Tumors of the Abdomen, 1885, p. 20, while recommending the tube less frequently than some other skilful men, mentions a case in which the patient died because he did not use it. The quantity of blood which he afterwards found in the pelvis was thin and dark—in other words disorganizing. The same writer in speaking of hysterectomy for fibroids, says: "Nothing has surprised me so much as the amount of almost pure blood that was removed from the pelvis in several of the cases that were drained. Where it came from in some of them remains a mystery to me." In the light of these facts, unless it can be shown that the use of a drainage-tube in itself involves more risk than does immediate closure, the responsibility for a fatal case of this character would rest upon the surgeon.

The chief objections that may be urged

[1] Read in the Section of Obstetrics and Diseases of Women of the American Medical Association, at Nashville, Tenn., May, 1890.

are: the danger of hernia or of fistula of the abdominal wall; the possible infection of the ligature or of the peritoneum; mechanical injury by the tube pressing upon viscera.

These points may be answered as follows: first, a small clean tube, removed in forty-eight hours, will tide over the period of chief danger from hemorrhage and will not, if well managed, interfere with the strength of the cicatrix by the end of the ordinary period of confinement to bed. If the tube be retained longer than this it is for some good reason which outweighs the increased danger of hernia. In cases where it is retained for weeks, it is because it has given exit to materials which would have infallibly caused death if not removed; and its use is vindicated.

The relation to subsequent hernia is an important matter. The tube must be kept clean and after its withdrawal a good closure of the opening be secured, either with a silver stitch previously untwisted, or by having the two lower stitches very close to a tube of small caliber. Far more important factors in the causation of hernia are the strain which results from leaving the bed too early and failure to properly support the abdominal wall with a bandage. Healing by granulation results in dense cicatricial tissue, but plenty of time must be given the process before intra-abdominal pressure is allowed to thin out the cicatrix. In one of the most successful operations of the day for the radical cure of inguinal and femoral hernia, the method of healing is in preference by granulation, but the patient is confined to bed six or eight weeks after the operation. Some of us have heard of laparotomy cases discharged from hospitals in two weeks.

Next to a fecal fistula, one of the most troublesome forms of sinus remaining after abdominal section is due to an infected ligature; and the possible influence of the drainage-tube in causing this infection is worthy of careful consideration. This accident has by some been attributed to the large size of the thread employed for the pedicle, but it has also occurred where the finest silk compatible with safety has been used. The thoroughness with which sterilization of this thread has been carried out before the operation is a matter for the conscience of the surgeon to determine; but an improperly managed drainage-tube is no doubt capable of infecting it. The claim is here made that such infection need not occur if proper care is used. The right management of a drainage-tube is indeed a matter of the greatest importance; and that some surgeons use a tube infrequently is doubtless owing to the fact that this part of the after-treatment cannot be personally carried out, but must be entrusted to others, too often without special skill and experience. As a choice of evils, no tube is better than a badly managed one.

Excessive pressure by the inner end of the tube has caused intestinal fistula. The usual recommendation for preventing this is that the tube should be raised half an inch daily, or oftener, and allowed to resume its place.

Another point of greater importance is lateral pressure caused by the sliding of the external dressing. If this is not watched, a powerful leverage pressure is exerted, especially by a rubber adhesive plaster dressing, the wound in the abdominal wall acting as a fulcrum.

Too much attention cannot be paid to the maintenance of an absolutely sterile area in and about the apparatus. The same precautions should be exacted from a nurse in emptying and dressing a tube as would be required in exposing the entire wound. Its caliber, whether or not filled with gauze or wicking, should be cleansed by some antiseptic solution, such as a saturated solution of boric acid, after the first forty-eight hours.

The mouth of the tube should never be stopped by a cork, as has been recommended, nor should a sponge be used as a cover. A large pad of absorbent cotton kept closely applied to the opening will serve perfectly to exclude the sources of decomposition; while all excess and dripping of discharge upon the rubber sheeting should be most carefully removed by a strong antiseptic solution, such as 1 to 1,000 mercuric bichloride; the rubber itself being occasionally removed for the purpose. It cannot be too strongly urged that the same rigid attention to cleanliness should be observed as in redressing a stump after amputation. One point in which nurses are careless is in handling the syringe. When the compression bulb syringe of Tait is used for suction, the bulb must never be compressed after the nozzle is put in the drainage-tube, but always before its introduction. Let the syringe be kept filled with an antiseptic when not in use; let the tube itself be light in weight and of small caliber; let powdered boric acid be used freely outside about the

main dressing where the tube comes through, if any moisture be present; let the tube be kept empty; when the discharge is slight, let the glass be replaced after twenty-four hours by a smaller rubber tube, slipped inside before the first is removed; and after another day let this be removed, its mouth having been kept well covered by absorbent cotton meanwhile. So managed, a drainage-tube is a safeguard and not a menace to the case.

A practical question is, when to drain. Certainly not in operations of the simplest character, which have been rapid in execution, where there have been no adhesions, little handling, no effusion and no pus. The cases where it is advisable are: where adhesions have been abundant and where oozing continues; where hemorrhage has been free and the patient is weakened; where the intestine is of doubtful vitality or where it has been stitched or resected; when the patient is old; when the peritoneum is diseased; when pus has escaped or a colloid cyst has ruptured; when there is septicemia or pyemia; when irrigation has been used; when much ascites is found. Finally, in all cases of doubt, drain.

A single case may be cited to illustrate the importance of drainage in septicemia. A woman who had been ill since an attack of puerperal fever nine months before, presented herself suffering greatly and with a tumor reacting to the umbilicus. Laparotomy disclosed an ovarian cyst containing nearly two quarts of pus, with abundant and most formidable organized adhesions to everything touched. The cyst wall was friable, dark and badly degenerated at several points where rupture would apparently soon have taken place into thickened and adherent bowel. The growth was with difficulty entirely removed. The drainage-tube was used for two days, nothing coming away but clear serum, though this was abundant for twenty-four hours. The patient recovered promptly and remains well. Notwithstanding that the day before operation the temperature was 104° and the pulse 150, the former did not exceed 99.5° in the two weeks succeeding the removal of the cyst. Now this woman, in my opinion, owed her life to the drainage-tube. Not because it carried off blood—for there was none; not because it drained a peritonitis—for there was none after the operation; but because in the poisoned condition of her system, as shown by pulse, temperature and emaciation, the quantity of serum removed by the tube would not have been absorbed, pus would have formed or peritonitis would have occurred and she would have lost her life.

TREATMENT OF DISEASES OF THE RESPIRATORY ORGANS WITH DRY INHALATION.[1]

BY O. A. DEAN,
SOUTH HAVEN, MICH.

The profession seems to have got far away from the old idea of sthenic conditions in diseases, in these as in other organs, demanding depletion and depressants, and to have settled rather upon the belief that all disease is asthenic. Pneumonia is no longer combatted (?) by blood-letting or hardly by veratrum, but is treated with stimulants, tonics and rest, which is another form of tonic. Typhoid fever is no longer starved or dried up, but is fed and stimulated and controlled. And if this be true in acute, much more is it true in chronic diseases of whatever nature, and I believe that those measures which have been most effectual are those which have had most of tonic element in them. Latterly the profession has had much to say of microbes, bacilli, cocci, etc., and has come to recognize that these low organisms flourish in asthenic conditions and unhealthy surroundings, and that our germicides have accomplished their object *pari passu* as these untoward concomitants have been eliminated. We have essayed to treat and to cure diseases of the mucous membranes, especially catarrhal, not by depletants but by stimulants and antiseptics of various kinds, at the same time building up the general strength by tonics. We have devised numerous instruments for applying sprays of various kinds, and the seller has been profited, perhaps the patient benefited, but how seldom cured; and they have left us after a time to submit themselves to the irregular practitioner who makes the most specious promises and charges the largest fee "for medicines only."

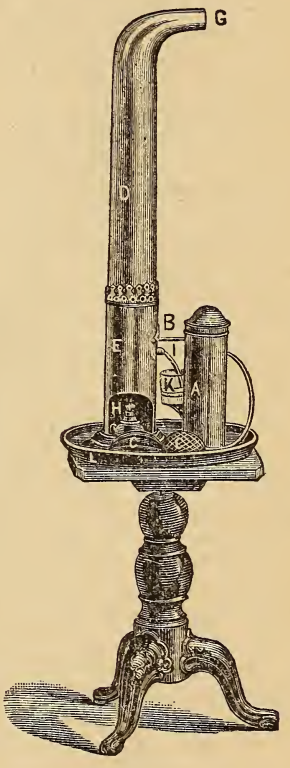
In view of our failures, the query is pertinent, would our efforts have succeeded if differently directed? We believe that in these catarrhal affections local applications are

[1] Read before the Section of Practice and Medicine of the Michigan State Medical Society, at Grand Rapids, Michigan, June 19, 1890.

necessary or very beneficial, but we know how difficult, nay impossible, it has been and is to reach the mucous membrane with any of the ordinary means. Our sprays might be good if they could be applied where wanted, but "there's the rub." In the nasal passages in favorable cases we could reach the inferior, and in a measure, the middle, sinus; but the superior scarcely at all. We could get a spray as far as the larynx, but only very sparingly into the large, and not at all into the finer bronchi; and so our antiseptics have failed to reach the abscess or vomica, or germ-laden bronchial tubes, and we have been obliged to depend on the general measures hinted at to accomplish our ends.

On the other hand, we have learned through our own, or the observations of others, that dry impalpable powders can and do penetrate to the finest ramifications of the air tubes and vesicles, as shown by the lungs of coal miners and others. Perhaps we have been made to realize it in our own persons after rides over dusty roads, or possibly in our younger days by standing behind a threshing machine, and expectorating dust for two or three days afterwards.

I therefore advocate to-day a trial of this method therapeutically. If we can deposit on the mucous membranes medicinal substances in impalpable powder, or in condensable vapor, we shall reach directly the diseased parts and produce effects upon them proportionate to the potency and strength of our remedy. The instruments which I have the pleasure of showing you are constructed for this purpose, and are the outcome of an idea of a Mr. Lindegaard, a photographer of Christiania, Norway, himself afflicted for many years with phthisis, who conceived the idea that nitrate of silver should be a remedy of value in that disease. To test the subject he had constructed a close room, the air of which he impregnated by some secret process with the remedy, and breathed it at stated intervals. He soon began to improve, and induced others to try it also; but the experiment was soon discontinued on account of the discoloration of the skin which resulted. Meantime he had become well and strong. Fifteen years afterwards he was drowned, and an autopsy was made by physicians who had known of his previous condition and recovery, who found firm cicatrices of former cavities, and evidences which satisfied them that they were the results of his experiments upon himself; and one of them expressed his belief that nitrate of silver in impalpable powder, the quantity of which could be controlled, would prove a wonderful remedy. Mr. F. Störmer, a civil engineer, to whom the remark was made, soon after produced an instrument which he called the "Störmer Norwegian Inhaler," of which this is a modification which seems to fulfil the requirements. It consists of a heater, partly of metal and partly of glass,



so constructed that air can be admitted at the base heated, and discharged at the upper orifice. Into this heated current of air a fine spray is thrown, through an opening provided for the purpose, from an atomizer. This spray is immediately vaporized, and if a liquid will be inhaled as vapor, or if a solid, will be crystallized and inhaled as a dry powder, in either case issuing in an invisible condition. To demonstrate the verity of the action I show you a card with spots made by exposure for specified times and to various strengths of nitrate of silver. This card was simply moistened with water that the dry crystals might the more easily adhere. On another card is seen the action of iodine upon starch, both demonstrating the

fact that the amount of impression is perfectly under control. That this impregnated air when respired reaches the fine bronchial tubes would be expected, and has been proven by experiments upon animals which I need not detail. Further than this, and as indicating that the scope of this method of medication may be broader than here set forth, it has been shown that inhalations of a mercurial salt have produced ptyalism; traces of iodide of potassium inhaled are found in the urine, and turpinal and santal give to the urine the characteristic odor of the violet, and modify catarrhal conditions of the bladder.

Though the apparatus was first intended for the administration of nitrate of silver only, and this still occupies the first place, various other medicines have been used, such as iodoform, phenol, phenol-camphor, iodine, etc. Among these, for the sake of brevity, I shall speak particularly only of the first. Experience with it has extended over some three years in Europe, by such men as Dr. Bidenkop, State Physician of Norway; Dr. Bugge, of Ringsacker, C. Blomberg, Physician in charge of National Hospital of Norway; Dr. Leij, member of the Society of Medicine, Society of Hygiene and Public Medicine of Paris, France, and others. The latter in October, 1889, wrote to Mr. Störmer as follows: "I have been using these last eight months your inhaling apparatus, and am very much pleased with the results. In all catarrhal affections, laryngitis, chronic bronchitis, pharyngitis, rhinitis, etc., its effects are remarkable, prompt and of incontestible efficacy. It is a unique and marvellously appropriate means of enabling inhalations of medicinal powder to be carried deeply into the respiratory organs, a result never before obtained. I believe that this power of deep penetration, being undeniable, if the bacteria and the bacilli of well characterized diseases must be attacked before they have time to infect the organism, it is with this instrument it should be attempted, and that with it one may hope to succeed." Later, in the *Bulletin de Thérapeutique*, March 15, 1890, Dr. Leij reports the clinical results of his use of the inhaler as follows:

"Since January 31, 1889, when we placed the Störmer apparatus in our clinic, we have subjected to this treatment one hundred and nine patients, whom we will divide into two classes, those having and those not having tubercles:

First Series.

Pulmonary phthisis	53
Phthisis of larynx	6
	59

Results.

Died	11
Cured	18
Relieved	15
Disappeared or stationary	9
Still under treatment	6
	59

"The eleven who died had reached the third stage of the disease, and only a few treatments were possible. As for the others the improvement was steady, and the average was three or four months with eighty or ninety treatments. The microscopical examinations of the sputa was made several times during the treatment for those having tubercles, and we found that, after five or six weeks, the bacilli had sensibly diminished, while in those cases pronounced cured they had altogether disappeared at the end of the third month.

Second Series.

Chronic laryngitis	19
Bronchial catarrh	14
Nasal "	5
Purulent pleurisy	3
Asthma	9
	50

"All the patients of this series have continued the treatment until cured, the treatments varying in number from twenty to thirty."

Eliminating in the first series the eleven cases which were too far gone to be benefited, and the six reported as still under treatment, there remain forty-one cases; and it is seen that forty-four per cent. of these were cured—a showing which no other method of treatment can make, and which may encourage us in the hope that some time some of the odium which has attached to our treatment of this dreadful disease may be removed.

The instrument is new in this country. In November, 1889, Mr. E. Hoell, exclusive agent of the Störmer Inhaler, established in Chicago an institute to demonstrate its use and effectiveness, employing a competent physician to diagnosticate and prescribe for

each case, and physicians were invited to call and to investigate or to send patients for treatment. In answer to my inquiries, Dr. B. M. Behrens, who first acted as physician in charge, wrote me, under date of May 12, that he had been highly impressed with the marvellous apparatus as being undoubtedly a thing with a great future. In the short time he had used it he had seen its best effect in atrophic conditions of nose and throat, and when the atrophic condition has been of not too long standing, with much wasting of tissue.

Dr. F. E. Crafton, of Chicago, endorses the language of a colleague abroad, who says: "We recognize the right of any one to inquire if the patients we consider cured are so in fact, and whether they may not fear a return of the disease. In most cases we have observed the process of the healing and cicatrizing of the lesions. We have satisfied ourselves by percussion and auscultation of the fact of the slow but steady and gradual disappearance of the pathological symptoms and of the bacilli, and after the lapse of many months, after the treatment has been stopped, these phenomena being still more manifest, we believe ourselves authorized to consider these cases cured."

Dr. B. Meyer, of Chicago, also expresses warm appreciation of the usefulness of the apparatus and method.

A partial list of patients treated at the Chicago Institute since January 1, indicates that every case treated has been relieved or cured, none remaining stationary or retrograding. The Institute being merely for the demonstration of the apparatus, the manager has made no special effort to let the work be known, except to the medical societies, physicians, etc.

My own experience with the inhaler is yet too limited to be of great value, but little more than a month having elapsed since I first saw the apparatus. I have prescribed its use in cases of catarrh, chronic follicular pharyngitis and bronchitis, and have used it in my own person for subacute and chronic laryngitis. Having been troubled for years with the chronic form, upon recently taking cold I suffered a violent exacerbation, attended with intense irritation and oppression of the respiration. A single treatment sufficed to relieve the violence of the symptoms, and three to restore me to about the usual conditions; but continuing the treatments in a rather desultory manner for the benefit of the chronic trouble, I have found my voice improving, so that I can now use it better than for a long time. In a similar case of one of my patients, where the patient was unable to speak aloud, the voice was restored in three treatments, whereas in previous attacks two or three weeks had been required for the same end. In every case that has come under my observation the patient has expressed gratification at the obvious effect as well as the agreeableness of the treatment.

The propositions of this paper, then, which I believe can be successfully maintained are:

1. By means of an impalpable dry powder, or a vapor-laden atmosphere, we may more surely reach diseased membranes than in any other manner.

2. Heated air is capable of holding medicinal substances in these forms, while they are conveyed to the extreme ramifications of the bronchi.

3. The effect can be proportioned to the susceptibility and requirement of each case by the strength of the solutions.

4. Heated air acts as a stimulant and assists the action of the contained remedies.

5. The Störmer Inhaler fulfills the indications for administering medicines in the form of powder or vapor.

6. Reports of its use thus far received indicate that it gives promise of great utility in the treatment of incipient phthisis and of nasal and bronchial troubles.

7. Its use does not preclude the administration of other usual remedies, but it may assist their action.

8. From the fact of absorption having been shown in a certain proportion of cases we may hope much in the way of systemic as well as local treatment.

As previously stated, nitrate of silver has been the principal agent used with this atomizer, because it is one of the best. It is given in solutions varying in strength from 1 to 1,000 to 1 to 100. The effect will vary with the susceptibility of the patient and the strength of the solution.

Not infrequently the inhalation produces perspiration, coughing, more or less violent, and at times a feeling of oppression across the chest, all of which soon pass away. If a strong solution has been used there may follow for some hours some irritability of the membranes, ending in increased and then decreased secretion. The general effect of the inhalations is rather exhilarating. In cases of acute coryza, simple sore throat,

or tonsillitis, the use of a solution of tincture of iron and chlorate of potassium checks it almost at once. In cases of diphtheria or croup it is obviously the best method of exhibiting our local remedies, be they simple lime water or sulpho-calcine.

I need not stop to enumerate the many remedies which may be used. The physician will not be at a loss to find something which he can use to advantage. Inhalations are usually made daily, although with some of the stronger solutions it is advisable to make them every other day. The sittings may vary from five to twenty minutes, but usually fifteen minutes is long enough with an equal interval of rest between.

EXCISION OF HEMORRHOIDS.[1]

BY CHARLES B. PENROSE, M. D.,
PHILADELPHIA.

My object in presenting this paper is to urge the more general use of Whitehead's operation of excision in the treatment of certain cases of hemorrhoids.

In 1887, Mr. Whitehead, of Manchester, reported three hundred consecutive cases of hemorrhoids which had been successfully treated by the method of excision and suture. His operation is performed in the following manner:

1. The patient is placed on a table in the lithotomy position, with the hips well elevated.

2. The anal sphincters are then thoroughly paralyzed by digital stretching.

3. The mucous membrane of the rectum is divided at its junction with the skin around the entire circumference of the bowel.

4. The mucous membrane, with the attached hemorrhoids, is dissected from the submucous tissue, and the cuff or cylinder thus formed is dragged below the skin margin.

5. The mucous membrane above the hemorrhoids is then divided transversely, thus removing the pile-bearing area, and the operation is completed by suturing the upper margin of the severed membrane to the free margin of the skin.

The advantages claimed by Whitehead for this method of treatment are based on pathological and on surgical reasons. He considers that the internal hemorrhoids, which are generally regarded as localized distinct tumors, amenable to individual treatment, are, as a matter of fact, component parts of a diseased condition of the entire plexus of veins surrounding the lower rectum, each venous radicle being similarly, if not equally affected by an initial cause, constitutional or mechanical. The operation of excision is the only one which removes this whole diseased area. It is, therefore, demanded for this pathological reason. It is, in addition, surgically more perfect than any other method of treatment, because it provides for the readjustment of healthy tissues with the object of securing primary union and rapid convalescence. It does not leave the sluggish ulcer of the cautery, nor is it attended with the pain and slow convalescence of the ligature.

My experience with this operation is limited to ten selected cases. Only those cases were selected in which there existed a complete circle of hemorrhoidal tumors surrounding the lower margin of the rectum, since for such cases Whitehead's treatment of excision seems to be most particularly adapted.

The details of the operation are simple and easy to execute. In dividing the mucous membrane from the skin it is best to begin at the posterior margin of the anus in order to prevent the blood from obscuring the field of operation. No skin should be sacrificed, even though there appear to be redundant tags around the margin of the anus. The skin always retracts somewhat and the tags shrivel and disappear before firm union has taken place. Failure to observe this rule may result in subsequent serious trouble. Kelsey reports the case of a woman who had been subjected to a so-called Whitehead operation and who presented herself to him with a complete circle of excoriated mucous membrane, extending for one inch outside the anus. It is probable that in this case the operator had sacrificed too much skin. On the other hand, the upper section of the mucous membrane should be made in the same horizontal plane throughout, in order to prevent subsequent ectropion ani. The dissection of the mucous membrane from the underlying tissue is exceedingly easy except in some cases of old—or long standing—piles. The attachment of the submucous tissue is very loose, and separation can be effected with

[1] Read before the Philadelphia County Medical Society, September 24, 1890.

the finger or with the handle of the scalpel. It is not always possible to dissect the piles completely from the underlying structures, as they may involve not only the mucous but the submucous tissues, and in such cases it is necessary to cut partly through the piles until the healthy mucous membrane above is reached. Repeated attacks of inflammation of course render closer the adhesion of the pile area to the underlying structures. In one of my own cases, where the piles had existed for forty years and had frequently been inflamed, the adhesions to the two sphincters were so close that a few muscular fibres were cut away during the removal.

The amount of blood lost during the operation is surprisingly small. Whitehead states that he has often operated on severe cases and not found it necessary to twist a single vessel. In five of my cases no hemostasis was necessary. Bleeding is avoided by adhering closely to the mucous membrane in the dissection, as the larger arterioles lie beneath the submucous tissue. The arterial bleeding occurs in those cases of old piles which have been subjected to previous operation or to attacks of inflammation, and in which dilatation of the rectal and anal arteries has taken place secondary to dilatation of the hemorrhoidal veins. The bleeding from the upper divided edge of the mucous membrane can be reduced to a minimum by following Whitehead's method of inserting the sutures as each portion is divided, or by adopting Marcy's plan of introducing a circle of shoemaker stitches of catgut around the mucous membrane above the piles before cutting the mass away. Whitehead's advice is in all cases to remove the complete cylinder of mucous membrane, whether or not the whole of this area appears to be diseased. He gives this advice for the reason which I have already stated, that he considers the individual piles as but part of a general pathological condition, involving all the lower hemorrhoidal veins of the rectum. Whether we accept this pathological view or not, it is best to follow this plan, and to make a complete circular division of the mucous membrane, as by this method the best surgical results are obtained and ectropion ani prevented. I have seen a case in which only one-half of the circumference of the mucous membrane of the rectum was removed, and a few hours after the operation an œdematous swelling formed in the other half, which has now resulted in a hemorrhoidal tumor almost as annoying as the one for which the operation was performed. In attaching the mucous membrane to the skin, Whitehead uses the interrupted silk suture. He never removes the sutures, but allows them to ulcerate through—a process which is very easily accomplished. In my own cases I have used the continuous catgut suture.

The treatment of these cases after operation is very simple. It is rarely necessary to use opium or the catheter. An opium and belladonna suppository introduced immediately after the operation, is in most cases all that is required. The bowels can be moved in from twenty-four hours to four days, and with very little pain. Absence of pain after Whitehead's operation is due to the thorough paralysis of the sphincters, and to the fact that no source of irritation is left beyond that of a clean linear incision, united without tension and without strangulation of tissue.

A glance at the histories of my own cases shows that they were all cases of aggravated hemorrhoids, in which the piles covered the whole circumference of the lower part of the rectum. In all the cases the disease had existed for many years, and two had been subjected to previous operation by the ligature. In only one case was there anything like free bleeding during the operation. In all the cases a suppository of one-half grain of extract of opium and one-half grain of extract of belladonna was introduced immediately after the operation, and this was all the opium required except in three cases, in which one-sixth grain of morphine was subsequently administered. The catheter was used in only three cases, and in these for a period not longer than twenty-four hours. The length of time the case is confined to bed depends to a great degree upon the social standing and the disposition of the patient. In my cases it varied from two to ten days. Every case should be able to sit up in four or five days, and to resume work in ten days or two weeks. The bowels were opened without pain in from twenty-four hours to four days after operation. No complications of any kind followed these operations. Union takes place quickly, and generally one dressing, taken off when the bowels are moved, is all that is necessary. In no case was there incontinence from paralysis of the sphincters, or any tendency to stricture, from contraction of the scar.

Since the publication of Whitehead's paper his method of operating has been tested by many surgeons. The operation cannot be criticised on surgical grounds, as it is certainly the most perfect plan of treatment, surgically speaking, which has been proposed. The immediate removal of the tumors, the coaptation of healthy tissues, and primary union, are substituted for slow strangulation by the ligature, or removal by the cautery and healing by granulation. The applicability, or the necessity, of this operation in all cases of hemorrhoids, is, however, open to criticism. If we accept Whitehead's views in regard to the pathology of piles, and believe that the whole venous plexus surrounding the anus and the lower end of the rectum, is in a pathological condition in every case of hemorrhoids, even though there may be present only one or two isolated tumors; then, of course, the complete removal of this area is indicated. But, that this view is not true is proved by the thousands of cases which have been permanently cured by the ligature and the clamp. The method, however, is indicated in all cases of aggravated hemorrhoids where the vascular tumors cover the whole or the greater part of the circumference of the bowel. In such cases the operation presents no great difficulties. Statistics show that it is at least as safe as operation by the ligature or the clamp, and it is certainly followed by a more rapid convalescence, and much less pain and discomfort.

STATISTICS OF ILLEGITIMATE BIRTHS.

BY WM. M. CAPP, M. D.,

PHILADELPHIA.

Statistics of illegitimate births, from the nature of the case, cannot always be accepted as accurate; yet in a general way they may be taken as indicating to some extent the social condition, the tone of morals and the state of education among the people at large. Under most of the governments on the continent of Europe, more attention than among us has been given to collecting data upon this subject and presenting it in suitable form for reference. Although the opinion seems to be prevalent that illegitimacy has been on the increase during the present century, careful students of statistical tables and of social conditions after investigation have arrived at an opposite conclusion, and hold that there is from year to year a gradual improvement in the matter. W. G. Lumley, in an endeavor to settle the question in 1862, went into a most elaborate investigation of the subject, using in his researches all the official information obtainable, and concluded that the proportion of such births in Europe was neither as great as popularly believed, nor was it as great then as it formerly had been. The results of his labors are published with many formulated statements in volume XXV of the *Journal of the Statistical Society of London.* Dr. Newsholme, in his *Elements of Vital Statistics*, published in 1889, gives tables upon the subject covering the period of 1876 to 1886 in England, and draws therefrom similar conclusions as to that country. Among many other subjects this one receives its share of attention at the hands of Alex. von Oettingen in his volume entitled *Moralstatistik*, published in 1882.

In London in 1866, the proportion of illegitimate births to legitimate was 3.9 per cent., or about four in each one hundred, and this was also the average rate for the years 1876 to 1886 inclusive. During the same period in all England, Newsholme places the average at 4.8 per cent., and at 4.7 per cent. for the year 1886; while Block, in his *Treatise on Theory and Practice of Statistics*, for the years 1865 to 1883, inclusive, finds it to be 5.27 per cent.; and von Oettingen for 1865 to 1878, inclusive, finds the average proportion for England and Wales to be 5.43 per cent. So also the rate for Edinburgh is 8.9 per cent., while for all Scotland it is 9.7 per cent.

The figures for these countries are remarkable chiefly as presenting a variation from the general rule, which almost invariably elsewhere shows higher figures for the cities than for rural districts and for the country at large. As reasons for this anomaly in Great Britain we find chiefly the complete system of poor-laws and the extensive establishment of alms-houses in the rural sections. In Scotland there is an additional reason in the peculiarity of the law which legitimizes any children which may have been born to a couple who afterwards are legally married. This has its influence upon women who are willing to trust to their ability in the future to induce the man to consent to a legal marriage in case children are born. As a rule it is found, as would naturally be supposed,

that many cases of pregnancy outside of wedlock find their way to the cities, because there more ample hospital provision is offered and shame is more easily hid in the crowd. Besides that, cities receive the tide of surplus and floating population in all countries.

Ireland presents an average of 2.73 per cent. for the years 1865 to 1878, inclusive, which is probably the lowest rate of any population of considerable size in Europe, of which we have data. This sustains the reputation which its women have long enjoyed. Certainly in our own land, to which so many of its young women have come, they have given no public cause of complaint, and in the matter of personal chastity compare favorably with any other class. In their own country it is said that deviations from rectitude in this respect so overwhelm the delinquent with reproach and shame—and especially in rural districts—as to make a continued residence there in most cases practically impossible. Emigration, however, is always a ready resource to cover up the evidences of the fault.

The figures of illegitimacy for continental cities in recent years are as follows:

Vienna, 50.6 per cent. in 1867; 41.9 per cent. in 1877; 44.1 per cent. in 1879.

Prague, 49.6 per cent.

Rome, 44.5 per cent.

Stockholm, 40 per cent.

Moscow, 38 per cent.

Paris, 28.5 per cent.—(in 1886, 24.42 per cent.)

Copenhagen, 25 per cent.

Brussels, 22.5 per cent.

St. Petersburg, 20.2 per cent.

Lisbon, 21 per cent.

The figures for continental countries are given as follows, the averages being chiefly for the years 1865 to 1883, inclusive:

Bavaria, 15.24 per cent.

Austria, 13.5 per cent.

Sweden, 10.17 per cent.

German Empire, 8.7 per cent.

Norway, 8.49 per cent.

Prussia, 7.50 per cent.

Hungary, 7.45 per cent.

France, 7.41 per cent. (In 1886, 8.2 per cent.)

Italy, 7.55 per cent. (Ranged in 1863 to 1879 from 6.7 to 8.4 per cent.)

Belgium, 7.08 per cent.

Spain, 5.53 per cent.

Switzerland, 4.78 per cent.

Holland, 3.49 per cent.

Thus it appears that while in the city of Vienna about 50 per cent. of all births were illegitimate, in Austria at large the percentage was 13.5 per cent.; and while Rome had 44.5 per cent., Italy together showed 7.41 to 8.4 per cent.; Paris had about 28.5 per cent. and France 7.41 to 8.2 per cent.; Brussels 22.5 per cent. and Belgium 7.08 per cent.; Stockholm 40 per cent. and Sweden 10.17 per cent.; and so with other large cities, all of which, as compared with countries, show much larger percentages of illegitimate births.

In Great Britain a majority of the births take place in alms-houses, and are of course among the pauper population, and a very large proportion of the mothers belong to the illiterate class, being unable to read or write their own names. It must be borne in mind, however, that there those of more intelligence can easily evade the true record against themselves if they are so disposed, and reports doubtless are inaccurate. On the continent, among the lower classes probably less shame is felt, and the authorities are more attentive to accuracy in recorded information upon this point.

In most of the large continental cities lying-in hospitals are freely accessible to all, and recently, with a view to lessen the frequency of the crime of abortion and to remove some of the temptations thereto, regulations have been introduced, in some of the more prominent in Germany, for the preservation of the utmost secrecy for such mothers as desire it, so that their identity is not disclosed even to the hospital authorities. Each patient is known only by a number given her upon entering, a duplicate of which is written upon a sealed envelope in which she has enclosed her name, the address of friends and any other items she may choose, and which is returned to her unopened upon her departure from the hospital without mishap. The child is taken with her, or may remain a ward of the State at her option.

The practice of keeping large standing armies discourages marriage, and some of the laws, by placing obstacles in the way, have had a similar effect and probably in a considerable degree have increased the proportion of illegitimate births; for, as has been shown by other writers, nature in her efforts to people the earth will not be thwarted, and population increases in spite of the artificial restrictions of convention or civilization. Indeed, as the foundling asy-

lums contribute so largely to the ranks of the armies, it has not been to the interest of the countries requiring large bodies of men to be constantly in camp and fortress, to strenuously discourage illegitimacy. The recognized system of concubinage in most of the large cities of Europe also tends to increase the proportion.

If the food supply is the ultimate factor in regulating the number of legal marriages in any given time in a country, it may in like manner influence the percentage of illegitimacy, as some of the statisticians have undertaken to show in their tables. Low wages, scarce food, little work and enforced idleness, may make the attainment of honorable marriage appear beyond reasonable expectation, and so offer an apology for license.

The official figures from which information on this subject is obtained, do not embrace abortions, premature births and still births. Allowances also are to be made for misrepresentations which render the records inaccurate. To this extent the statistics come short of being worthy of absolute reliance.

In our own country statistics upon the subject are not obtainable, or if so, cannot be relied upon for accuracy, owing to loose methods in recording them, and to the facilities allowed for misrepresentation, which, on account of public opinion, is most generally resorted to. Hence comparisons cannot be made with other countries. Doubtless the general absence of foundling asylums, the restrictions often imposed in the admission to lying-in hospitals, and a general feeling of aversion to delinquent mothers and fatherless children cause the crimes of abortion and infanticide to prevail more among us than in countries where more practical and broader ideas of charity and more unprejudiced impulses of humanity are in vogue.

In Philadelphia, up to the present time, no efforts have been made to keep records upon the subject except for the years 1888 and 1889. In the former the total number of births was 26,296, of which 649 or about 2.8 per cent. were reported as illegitimate; in 1889 the total number was 27,491, of which 814 or about 2.9 per cent. were illegitimate.

—Euxanthone, the coloring principle of the very expensive yellow Indian dye known as piuri, has been artificially prepared by M. Groebe, a Swiss chemist.

Foreign Correspondence.

LETTER FROM ENGLAND.

Shrewsbury, September 3, 1890.

"The bold situation of the town, girdled by the health-bearing breezes of a beauteous river, gives a striking and majestic appearance to Shrewsbury." The foundation of this town goes back to about the year 600, and it is about the only town in England which was not founded by the Romans. The ancient history of this city is particularly interesting. One of the most decisive battles in early English history was fought here. Shakespeare in his "Henry the Fourth" mentions it. The ancient black and white houses are probably as interesting to one from the new world as Melrose Abbey or the walls of Chester. These timber houses, of which there are many, date back to 1500. Many have dates placed upon them telling the year in which they were built. I noticed several 1505–1534, etc. They have projecting stories sustained by elegant brackets and the angle uprights enriched with small pointed arches carved with trefoil, the wood black and interspaces of white plaster. Shrewsbury is not on the line of the ordinary route of travel; and the globe-trotting American has not as yet found out its beauties, and much less would one expect a wandering physician or surgeon to turn his footsteps towards this very ancient and unique English city, to find anything new or novel in his line of work. And yet the town is not without its medical history; for here Henry I (1100) built a church where services were held for a *hospital* of lepers. St. Giles's Hospital was originally established for the reception of persons afflicted with leprosy, which disease was brought back from Palestine by the Crusaders. Henry II granted to it thirty shillings yearly (about $400 of modern currency) of the rent which he received from the sheriff of Shropshire, towards the support of the infirm or diseased occupants. While leprosy is a disease not known in England to-day, yet the original grant of money is still paid; for "the poor ye have always with you." Shortly after the founding of the above hospital Earl Roger de Montgomery built and supported an infirmary within the precinct of the Abbey "as an asylum for diseased and superannuated monks," a fragment of which building yet remains. The present hospital is a large, commodious building with all the

modern conveniences, where aseptic surgery is just as successful as the antiseptic. At the top of the building, on a tablet, is the following inscription:

Salop Infirmary.
Established 1745.
Supported by Voluntary Subscriptions and Benefactions.
Rebuilt 1830.

The eye and ear hospital was founded in 1818. To-day one of the finest and most thoroughly equipped buildings in the kingdom occupies the place of the old one. It was found that its usefulness necessitated a larger building, and the Board of Trustees in 1881 built the present hospital.

Dr. Wm. Charnley, the surgeon to the institution, is best known to fame as the author of the article on Retinoscopy in Morton's book on Refraction. Dr. Charnley's reputation, among the English writers on refraction as a master of mathematics, is so high that he has during the last few years corrected and revised no less than three well-known treatises on refraction. Dr. Charnley, like many others who have given retinoscopy some years of trial, finds that it is not easy to learn nor easy to execute; and, while it may be of undoubted advantage in cases of illiteracy of young children, and in hospital work, yet in private practice it is useful only in confirming what trial lenses have already told one.

The number of new cases applying for relief at the hospital here this year has been about two thousand. There have been two hundred and sixty-five chief operations, including forty-seven extractions of cataract and forty-eight iridectomies. Of the cataract operations, forty-four were followed by good vision. Dr. Charnley, in performing cataract operations, makes a modified Graefe cut with a very small iridectomy. The patient's eyes are immediately bandaged with very light aseptic dressings. After twelve hours these dressings are removed, the lower lid of the operated eye is depressed to allow the accumulated tears (if any) to escape; then the eye is bathed with a mild boric lotion, followed by one instillation of atropine (four grains to the fluid ounce). The eye is not examined for twenty-four hours, when a similar treatment is applied. After three days the bandages are dispensed with, the patient only wearing a shade, the light in the room being modified by blinds. As is usual with all careful surgeons, the first two dressings are made by Dr. Charnley; the trained nurse looks after the subsequent treatment. Dr. Charnley regrets that his success in chronic glaucoma has been almost nil. The subconjunctival operation is performed for strabismus. The full emmetropic correction is given, and the glasses are ordered to be worn constantly. Ulcers of the cornea are treated with that standard remedy, yellow oxide ointment, a fuller strength ointment, with atropia sulphate combined, being prescribed. Some observers have noted the predisposition of the Welsh nationality to *retinitis pigmentosa*. At this hospital, where at least one-third of the patients are Welsh, this disease is not common. A curious case of connective-tissue growth in the fundus oculi presented itself on the day of my visit. The singular part of the young man's history was, that he discovered only two days before that he was totally blind in that eye (the left one). An examination with the ophthalmoscope revealed the growth. Had this young man received an injury to that eye, he would have been under the impression that the injury had caused the loss of vision. Yet he had never used his left eye since birth, as it is now well understood that such growths are embryonic.

The management of this hospital is most excellent, and, to prevent an indiscriminate abuse of its charity, every patient is obliged to bring a recommendation from some annual subscriber that he is deserving and worthy. Accident cases are exempt from this rule. They, however, after one treatment, are obliged to conform to this regulation. A private ward is in use for patients who can pay. The institution, being essentially a charitable one, is kept for all the purposes for which it was founded; and, in justice to the "proud Salopians," it is not abused.

L. Webster Fox, M. D.

Child Suicides.—From January 1 to September 1, 1890, 62 children—46 boys and 16 girls—committed suicide in Berlin. Of this number 24 had attained the age of fifteen, 14 their fourteenth year, 9 their thirteenth, while 7 were only twelve years of age, and one had not attained the age of seven. In most of the cases the immediate cause for the act remains a secret, but it is supposed to have been due to exceptional severity on the part of servants or teachers.

PERISCOPE.

Treatment of Pertussis with Bromoform.

Dr. Louis Fischer, attending physician to the Children's Department of the German Poliklinik, New York, says, in the *Medical Record*, September 6, 1890:

Bromoform, $CHBr_3$, is a colorless liquid, boiling at 151° C., and solidifying at 2.5° C. Its specific gravity is 2.83 at 0° C. It is produced by the action of bromine upon alcohol in the presence of an alkali. In practice milk of lime is saturated with bromine, alcohol added, and the mixture distilled. In 1849 Nunneley and Schuchard called attention to bromoform as a possible anæsthetic, and in 1869 Rabuteau brought the drug forward as a new anæsthetic.

Given to the lower animals by inhalation or hypodermic injection bromoform produces rapid narcosis, in which, according to the researches of Von Horoch, the breathing is not noticeably lessened and the pulse remains full, regular and strong. Although the blood-pressure is distinctly reduced, the heart is said not to suffer from the influence of the drug, and the peripheral vagi are not affected. Further, as powerful irritation of a sensory nerve has no influence upon the blood-pressure, it is probable that the fall is the result of vaso-motor paralysis, which is confirmed by the rapid sinking of the temperature. The excitability of the cerebral psycho-motor centres and the general reflexes are entirely destroyed. Von Horoch has used the bromoform as an anæsthetic in several cases in man. The most marked symptom was excessive cyanosis of the face. The urine passed after recovery contained bromine.

More recently Dr. Stepp, of Nuremberg, applied bromoform successfully in the treatment of whooping-cough, and still more recently Professor Senator, through his assistant, Dr. Loewenthal, of Berlin, published an article in the *Berliner klinische Wochenschrift*, heartily endorsing Dr. Stepp's treatment and recommending its further use, promising to again publish his results. He noticed in some cases a decided benefit as early as the second day of treatment, in others on the third or fourth day, depending on the severity of the case. Vomiting disappeared in the first week of the bromoform treatment. Bronchitis, complicating tussis convulsiva, seemed to be benefited also during the course of the treatment. In from two to four weeks children were usually discharged cured. Appetite also was better during the course of treatment. Children with previous morbilli, also delicate ones, experienced equally beneficial results. Some cases had the treatment interrupted by a complication setting in, *e. g.*, morbilli, pneumonia or varicella. Relapses occurred where bromoform was not administered long enough; in some cases sleepiness was observed during the course of treatment. In a case where a toxic dose of $CHBr_3$ was given, the following symptoms were noted: Contracted, pin-point pupils; small, compressible pulse; pale countenance; cornea not reacting; on auscultation long, deep inspiration; hardly any expiration was noticed; the heart-sounds were scarcely perceptible. The child reacted immediately on giving a hypodermic injection of sulphuric ether.

He describes sixteen cases to show the effect of bromoform in his practice, and adds that the cases illustrate the different conditions of children attended; patients of all kinds were taken at random, although most cases were seen in the Children's Department of the German Poliklinik; several cases were also seen in the New York Polyclinic. Most patients that were treated lived in tenements, in badly ventilated apartments, and were, as a rule, poorly nourished subjects, as are usually most dispensary patients. Several cases with the best hygienic surroundings possible, with excellent nursing, the best of food and strict sanitary regulations, were also attended, and Dr. Fischer could notice no more benefit than he did in the ordinary class living in tenements. He does not pretend to say, however, that, given the best hygienic surroundings, the best of care, proper dieting, etc., such cases might not, in the long run, be much easier treated, although in fifty-one cases he noticed no shortening of the disease where better food and air were added. In all his cases he made it a rule to urge the mothers or the nurses to count the number of attacks of coughing in a given time, say six, or usually twelve hours, as only by knowing exactly how many times a child coughed could the treatment be regulated. He also had the number of severe and the number of mild attacks counted. In giving bromoform after eating, he refers, in cases of infants, to giving it after nursing; but it made no particular difference whether it was given shortly

after feeding or an hour after feeding. In several cases he gave bromoform before meals, and noticed no bad effects from the same, although giving it after feeding was preferable. Baginsky, after going into detail about the etiology of tussis convulsiva, sums up by saying that it is an infectious catarrh, caused probably by a micro-organism, which has not as yet been found. There is no question, however, as to the infectious nature of whooping-cough, and children all through the treatment should be isolated from healthy ones as thoroughly as possible. Dr. Fischer has in all used bromoform in fifty-one cases, and still has several under observation; and thinks there is no question but that it is the best known remedy when properly applied. Owing to its discoloration and extreme volatility, he has administered it from dark bottles, or bottles protected from the light and very well stoppered. If the bromoform turns brown, then it contains free bromine and should not be administered.

The doses required were the following: For children under and up to one year of age, two to three drops three times a day; children from two to four years of age, three to four drops three or four times a day, depending on the severity of the case; children until eight years of age, four to six drops three or four times a day. The doses were usually increased on the third day, sometimes after the fourth day of treatment, and in very severe cases on the second day of treatment, by gradually adding one drop to the usual dose. The time required for a cure was variable; in some cases ten days of treatment was enough to effect a cure, others required almost four weeks. About seventy-five per cent. could be discharged cured between two and three weeks after steady treatment, where no other complications existed.

Bromoform should be given in a small teaspoonful of water. Owing to its weight it sinks to the bottom of the spoon, and great care must therefore be taken to see that the child swallows the bromoform, and that this does not remain in the spoon. Dr. Fischer did not experience any difficulty in giving it to children, as bromoform has a pleasant taste and was very readily taken by such patients.

Death from Paraldehyde.

The *Lancet*, August 23, 1890, reported that on August 10, a patient in the Fever Hospital attached to the Cork Workhouse died from the effects of paraldehyde. The deceased, twenty years old, was suffering from typhoid fever, and but slight hopes were entertained of her recovery. As she was suffering from violent delirium and sleeplessness, a hypnotic was prescribed, and the temporary nurse overlooked the directions she had received, and, instead of giving one teaspoonful, administered from six to seven teaspoonfuls. In about five minutes the patient fell into an unconscious state, and, despite medical assistance, remained in that state for four hours, when she died. The quantity of paraldehyde that was administered is not mentioned, but it may be supposed the deceased girl took from six to seven drachms.

Effect of Exercise.

Dr. Thomas M. Bull, in the *New York Medical Journal*, August 9, 1890, says: The high grade of general health which a proper amount of exercise tends to develop is the best possible safeguard against the encroachment of morbific germs. This is shown well in the case of ordinary colds. I have repeatedly seen people who, before taking exercise regularly, were afflicted with colds nearly all the time, but afterwards had a great many fewer or none at all. And right here I should like to mention a little plan to avoid taking cold when exposed to a draught. Many of us are frequently exposed to draughts when we are in company and cannot avoid them. If a person in this position would rapidly and strongly contract the large body muscles, or opposite plates of those attached to the limbs, by means of which a great deal of force may be exerted and but little motion caused, he will have no fear of a draught producing a chill. By contracting in this way the muscles which cause adduction of the arms while the arms are at the side, I can in a short time produce a very comfortable state of perspiration, and certainly ward off any bad effects of a draught.

In regard to the effect of exercise on diseases of the heart, I have seen cases which were diagnosticated by several physicians as mitral regurgitant gradually grow less prominent and disappear. I have often seen cases where the heart sound was roughened, accentuated, or indistinct, improve rapidly and acquire a perfect sound when the only change was in taking regular exercise. In

the case of hearts, when the only trouble was excessive rapidity, intermittency, or irregularity, I have seen improvement follow very rapidly. And I believe that one of the best prophylactics against the development or extension of almost any hereditary or organic disease is muscular exercise properly taken. And, in conclusion, I should like to say that, in my opinion, the value of exercise is not exceeded by that of any single therapeutic measure. I am certain that all of us have seen patients for whom it would do more than any other thing consistent with their lives and occupations.

And if we were able to intelligently prescribe, and so get all the good possible out of exercise, I am confident we should be able to do many patients more good than in any other way.

Purgative Treatment of Peritonitis.

In a paper on the "New Treatment of Peritonitis," in the *Kansas City Medical Index*, July, 1890, Dr. Emory Lanphear strongly advocates the abandonment of the old method of rest and opium and the adoption of purgation with saline cathartics or operation. He specially cites the practice of Dr. John H. Musser, of Philadelphia, who gives a summary of twenty-six cases treated with small doses of calomel, olive-oil enemata, etc., without opium (except one or two small doses of morphine and atropine when pain was excessive); nineteen recovered without surgical interference, four convalesced after laparotomy, and three died. His method consisted in local blood letting until pain is much relieved; if more than forty-eight hours have elapsed, a blister; liquid diet absolutely; stimulants administered freely to prevent collapse; cracked ice, lime-water and iced champagne for thirst, if desired, but sips of hot water or hot whiskey are better; calomel in small doses hourly until the bowels are moved freely; veratrum or aconite for fever; whiskey, digitalis, atropine and amyl nitrite if collapse be imminent. While Dr. Musser's cases did not receive salines, the plan of treatment was the same—that of purgation instead of opium—and the results were startingly favorable, for of these cases fifteen were desperately ill at the first visit of the doctor.

Many more cases, especially following laparotomy, might be given with like favorable results, but these suffice to show that prominent men are changing from the opium to the purgative treatment of this disease, and with a greatly decreased mortality. Recalling, then, the experience of my preceptor, remembering my own cases and adding thereto the accumulating weight of evidence, my conclusions are that the saline treatment should be adopted early in simple, acute peritonitis; that small doses of calomel may be given to mild purgation in cases seen after the disease is fully developed; that cases which fail to be relieved by cathartic measures should receive early operative interference; that whenever peritonitis has gone on to that stage where the formation of pus is known, or even suspected, to have taken place, abdominal section and drainage are imperatively indicated; that when the existence of tubercular peritonitis is diagnosticated, or strongly suspected, operation (exploratory incision) is justifiable.

Opium is only indicated in the second stage of peritonitis, and then not because it "forms a splint" but because it relieves pain, sustains the heart and prevents shock—thus combatting the tendency to death.

Atropine and Potassium Cyanide.

The *Western Druggist*, August, 1890, says a young man at Halle, Germany, recently attempted suicide by swallowing a fatal dose of potassium cyanide in solution, and to make assurance doubly sure, followed it up by a solution of atropine. This, however, was too much of a good thing; the two deadly poisons had it out between themselves, and the rash court scribe, after a few fainting spells and a sense of weakness, was discharged from the city hospital on the following day none the worse for his physiological experiment. He received no medical treatment.

Pasteur Statistics.

The Pasteur Institute in Paris reports (*Bulletin Médical*, August 17) that 172 persons were treated during June, 1890. In 57 cases the rabid conditions of the biter was tested experimentally (according to Pasteur's theory); in 80 cases it was asserted by veterinary surgeons; in 35 the animals were only "suspected" of rabies. The animals that did the biting were: dogs, 154 times; cats, 7 times; horses, 7 times; asses, 3 times. In one case the bite was by a child affected with rabies.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

MIXED ANÆSTHESIA.

Since Nussbaum, in 1877, proposed the hypodermic injection of morphine previous to the induction of anæsthesia by chloroform, there have been a few who resorted to this procedure. More recently Dastre, a French surgeon, has recommended a combination of morphine and atropine for the same purpose. In *Le Mercredi Médical*, July 30, 1890, Reynier reports a very unfortunate experience with this use of morphine and atropine previous to chloroform anæsthesia. Dastre maintained that the syncope produced by chloroform is due to the inhibiting action of the pneumogastric and of its centres in the medulla, and therefore proposed to paralyze this apparatus with morphine and atropine. Aubert obtained satisfactory results in experiments upon men, and it was owing to these that Reynier tried the method. The patient was a young girl, sixteen years old, pale and chlorotic, who underwent a short operation for tuberculous osteitis. It was over in ten minutes. She had inhaled about seven drachms of chloroform and had received previous to anæsthesia one-twelfth of a grain of morphine and one two hundred and fiftieth of a grain of atropine. The operation over, sleep was prolonged. Reynier says he was not uneasy, for Dastre said that this was the rule and was one of the advantages of the method. Reynier therefore left the ward, but in about two minutes his interne summoned him in haste. The respiration of the patient had abruptly become more rapid, then soon afterwards very feeble, and when Reynier arrived it had almost ceased, and so had the heart beats. For three hours artificial respiration and hypodermic injections of caffeine were used; at times it was hoped that some spontaneous respirations were obtained. But there was no help for it; the patient was dead. The autopsy, conducted by Verneuil, disclosed nothing abnormal. The chloroform was analyzed and was found pure.

Reynier expresses the opinion that there was a progressive intoxication of the centres in the medulla by the chloroform, and that the morphine and atropine deprived the chloroform of one of its advantages, namely, its rapid elimination. He has endeavored to prove this opinion experimentally in the laboratory. He thinks that dogs bear atropine and morphine very well, but chloroform badly; whereas just the reverse is true in man, who bears chloroform well, but morphine and atropine badly.

It should never be forgotten that even the safest anæsthetic is dangerous. But experience in the administration of an anæsthetic goes far to lessen its dangers. Perhaps the surgeon will have the fewest accidents who confines himself to one anæsthetic and so studies the administration of that one that he becomes master of it. Chloroform is undoubtedly more widely used than any

other anæsthetic agent. The path by which death takes place after its use is still in dispute, and until that is determined beyond question it will be hard to decide what part of mixed anæsthesia—if any—is directly responsible for a death following it. Deaths attributed to chloroform alone are too common and mixed anæsthesia has been used with entire success too often for the case described above to be regarded as proving that it is more dangerous than useful in surgical practice.

BITE OF ANIMALS APPARENTLY NOT RABID.

Drs. Roux and Nocard, assistants of Pasteur, have recently been endeavoring to answer conclusively the question whether or not a person bitten by a dog which, at the time of the biting, shows no symptoms of rabies, but which developed plain manifestations of the disease three or four days later, runs any risk of becoming rabid.

They conducted a series of experiments the result of which are reported in the *Annales de l'Institute Pasteur* No. 3, 1890, and are quoted in the *Wiener Medizinische Presse*, July 13, 1890. An "emulsion" of the spinal cords of rabid dogs was injected into the anterior chamber of the eyes of healthy dogs, and as soon as the latter showed the first symptoms of rabies—an elevation of temperature—their saliva was injected into rabbits and guinea-pigs. The saliva of the rabbits and guinea-pigs was found to be virulent three days before any symptoms of rabies had become manifest. The question now arose whether or not the seat of injection (the anterior chamber of the eye) favored the rapid infection with the saliva. Subcutaneous inoculations were then tried, and it became evident that the saliva was virulent thirty hours before the appearance of the first symptoms of rabies. Finally, in subdural inoculations the saliva remained inert for seven days and became virulent synchronously with the appearance of rabies in the animal. The amount of virus in the saliva increases with the advance of the disease. Roux and Nocard claim, therefore, that the result of their experiments show that a dog may be considered dangerous three days before any symptoms of rabies have manifested themselves.

This is a perfectly typical example of the mode of reasoning of the Pasteur Laboratory, so far as the account we have seen goes. There is no evidence whatever that any of these animals experimented on had rabies, or that any of them ever had any of the symptoms of what the Pasteur disciples *call* rabies, except an elevation of temperature; or that any control experiments were made to show what effect would be produced by inoculating saliva from animals which had not been sickened by the method used in Pasteur's Laboratory to produce the artificial disease which there is called rabies.

It is a simple announcement in true Pasteur style, unaccompanied by proof of its reliability and calculated to increase a foolish fear which has proved already very dangerous to the world and a source of great profit to Pasteur. It is calculated to arouse the anger of those who labor to heal diseases, when they see these experimenters launching one dogmatic assertion after another, to multiply cases of a disease which was less frequent and less fatal before ever they meddled with it.

THE IMMEDIATE REPAIR OF LACERATIONS OF THE PELVIC FLOOR.

Although this subject has been before the profession a long time, we believe that very erroneous views prevail only not concerning the repair of injuries of the pelvic floor, but more especially concerning the nature and frequency of such injuries. It is still not unusual to hear the gravity of such injuries measured by the number of fractions of an inch of skin involved in the lesion, and to hear it gravely proposed to repair the same by introducing one suture. Until the real nature of injuries of the pelvic floor is in-

vestigated by the practitioner, and the extent to which the muscles of the perineum, and more especially the levator ani, are involved in each injury, so long will inefficient means be recommended in the treatment of these lacerations.

In the *Medical Record*, of August 30, 1890, Dr. Irwin H. Hance contributes a well-written article on this subject. He divides lacerations of the pelvic floor into three classes: 1, Median; 2, those involving the skin over the perineum and extending up one or both sides of the median line of the vagina; and 3, lacerations of the posterior vaginal wall without rupture of the skin—tears usually V-shaped, one arm of the V being longer than the other. Had Dr. Hance added, as a fourth-class, laceration and over-stretching of the levator ani muscle, without superficial laceration of either mucous membrane or skin, his classification would be complete. The emphasis given the fact that simple median lacerations form an inconsiderable portion of the injuries of the pelvic floor, is specially to be commended, since this fundamental fact has a positive bearing on treatment.

In repairing these lacerations Dr. Hance insists upon the fact that the parts are to be sutured in their normal relations. To accomplish this, suturing is begun at the upper extremity of the tear—as in the secondary operation. He uses catgut, and insists on rigid antisepsis. This method of operating is unquestionably the only one which brings the severed tissues together in proper relation—with the exception perhaps of simple median tears which extend only a fraction of an inch up the vagina; and in these cases suturing is of little importance. Imagine the closing of a laceration extending one or two inches up the vagina, perhaps on both sides of the median raphé, and involving the levator ani, by sutures introduced from the skin surface of the perineum! One of two results must follow. Either the suture acts as a drawing-string and distorts the relation of the parts, or else it fails to embrace the upper extension of the tear and leaves a pocket for the collection of lochial discharge. The choice of suture material is largely indifferent, as good results can be obtained with any reliable antiseptic solution, provided only that it is properly introduced.

It is high time that the immediate operation for the repair of lacerations of the perineum be properly conducted, and the practitioner cease to waste his time in drawing together a useless fold of skin before the injury of real importance—the lacerated levator ani muscle.

HERMAPHRODITISM, OR SEXUAL PERVERSION.

In the early part of September the newspapers contained an account of a case which was calculated to stimulate curiosity, and to excite interest in the mind of the general public. It was that of an hermaphrodite, or else of a sexual pervert. As the *Philadelphia Record*, September 3, tells the story, "Delbert Reynolds was born a boy twenty-two years ago at San Rafael. A short time ago he married a respectable blacksmith at Alena, and blossomed forth as Belle Hardman, a loving wife. Her husband is willing to make affidavit that she is a true woman, and the mother, Mrs. Reynolds, is prepared to swear that it was born a boy, and remained so for twenty years, doing boy's and man's work and associating with males as a rule. The transformation covered a period of eighteen months, and a San Francisco doctor, while amazed, vouches for the marvelous change of sex as an absolute fact. The only solution of the problem will be for he, she or it to become a mother. In the meantime the doctors, the neighbors and all the country round are asking, 'What is it?'"

We have investigated this case through a correspondent in San Francisco, and have learned from the family physician at San Rafael, Dr. Henry A. Du Bois, that he had never had his attention called to any mal-

formation in the young man, and had never examined his genitalia. Until lately the person had been considered a boy, and is said to have hair on his face. He is said to have married a young man, and to be living with him as his wife. Dr. Du Bois thinks he is a male, and that the present association is due to unsoundness of mind, or that it has been made in order to attract attention. It is said that the subject of this notice has refused to submit to a physical examination, and that his mother and friends regard him as a male.

It is to be hoped that more precise information will be obtained in regard to this case; because it will be interesting to know whether it is really one in which it is possible for a mistake to be made as to the sex of the individual, or one in which sexual perversion or a desire for notoriety has led to the union of two males.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

THE PULSE. By W. H. Broadbent, M. D., Senior Physician to, and Lecturer on Clinical Medicine in the Medical School of St. Mary's Hospital, London. Illustrated with fifty-nine Sphygmographic tracings. Small 8vo, pp. vi, 312. Philadelphia: Lea Brothers & Co. Price, $1.75.

The author modestly states in the preface that this little book is for the most part a reproduction of the Croonian Lectures on the Pulse, delivered before the Royal College of Physicians in 1877. There are, however, some amplifications and additions, in particular of a chapter on the sounds of the heart.

After an interesting historical sketch of the pulse, the author takes up the consideration of the pulse, its production and significance. He declares that it is not an expansion of the artery with each so-called "wave" of blood, but that it indicates simply the degree and duration of increased pressure in the arterial system caused by the ventricular systole. The term "tension" means simply the degree of fluid pressure within the artery, putting its walls on the stretch. Arterial tension and blood pressure, therefore, mean exactly the same thing.

The three factors in the pulse are: the action of the heart, the elasticity of the great vessels, and the resistance of the arterioles and capillaries. The heart determines unconditionally the frequency and regularity or irregularity of the pulse, and, with certain qualifications, its force or strength. The great vessels act as an elastic reservoir and convert the intermittent jet issuing from the ventricle into a more or less continuous stream, impressing at the same time certain characters upon the pulse according as the elasticity of their walls is perfect or impaired, and according as they are kept fully distended or only slightly on the stretch. The capillaries and arterioles, in their turn, by the varying resistance which they offer to the passage of blood through them, determine the mean pressure maintained in the arterial system and the character of the pulse, and influence materially the action of the heart.

After a chapter on the mode of feeling the pulse, the author takes up in successive chapters the heart-sounds in relation to the pulse: increased frequency, diminished frequency, intermittency and irregularity; the pulse as influenced by variations in artero-capillary resistance; low arterial tension; high arterial tension; the pulse in acute disease, in valvular disease of the heart, in structural disease of the heart, in aneurism, and in kidney disease. The concluding chapters are on Intermittent Albuminuria, and the Pulse in Affections of the Nervous System.

This brief statement of the scope of the book will give a good general idea of its contents. In speaking of the pulse of aneurism, Dr. Broadbent adopts the general view that a difference between the two radial pulses and a wave-like sphygmogram is significant of aneurism. Von Ziemssen has shown that this difference is the result of a narrowing of the orifices of the vessels coming from the arch, produced by atheromatous change, and that, while such narrowing may be found co-existing with aneurism, it is more frequently found apart from it in general arteritis deformans.

One who has not himself given close study to the pulse will be surprised, on reading Dr. Broadbent's book, to learn how much the pulse may indicate, and how important its indications are in the detection of disease. Perhaps no more hopeful sign of the progress of medicine could be given than this monograph; it shows how broad is the field of medicine, and at the same time how much is to be found in a small corner. We cordially commend the book to our readers.

LEÇONS CLINIQUES SUR LES MALADIES DE L'APPAREIL LOCOMOTEUR.

CLINICAL LECTURES UPON DISEASES OF THE LOCOMOTOR APPARATUS (BONES, ARTICULATIONS, MUSCLES). By Dr. Kirmisson, Professor Agrégé of the Faculty of Medicine, etc. With 40 illustrations. 8vo, pp. viii, 550. Paris: G. Masson, 1890.

The author succeeded Professor Richet, in 1888–89, in the chair of Clinical Surgery at the Hôtel Dieu, where the lectures from which the present volume is made up were delivered. As indicated in the title, only the lectures on diseases of the bones, articulations and joints have been utilized in this way. The subjects treated include osteitis, osteomyelitis, hereditary syphilis of the bones, chronic inflammation of the joints (shoulder, hip, knee), syphilitic arthritis, Pott's disease, hydatid cysts of muscles, club-foot in its several forms, etc. The book gives an admirable presentation of the diseases named from a modern French point of view, and is a valuable addition to current surgical literature.

Burials without Death Certificates.—It was lately stated in the British Parliament that fifteen thousand persons are buried annually without any medical certificate of death. The government has promised to inquire into the matter.

New Remedies and Appliances.

In this department, notice will be given of Remedies, Food Articles, and Instruments or Surgical Appliances of which specimens are sent to the Editor; it will bear the same relation to these articles that the department of Book Reviews now does to books.

Wyeth's Beef Juice.

It is seldom that a dietetic preparation so thoroughly agreeable as Wyeth's Beef Juice is put upon the market. It is decidedly the most palatable beef extract which we have ever examined. For its preparation nothing is required except the addition of a teaspoonful of the beef juice to about half a glass of cold water; and this makes it very convenient for administration. As compared with such preparations as Valentine's beef, it is very superior in nutritious quality, and we think that no one who has used that will regret it if he puts Wyeth's Beef Juice in its place.

Correspondence.

Fences against Malaria.

To the Editor.

Sir: Under the quaint title of "Fences for Malaria," there is a paragraph in the Reporter of September 20, 1890, in which the use of leafy hedges for intercepting malaria is referred to as an old and popular notion. To the fact that this notion is well-founded there is much testimony that is both interesting and curious. The readers of that charming series of lectures known as *Watson's Practice of Physic* find much in his discourse on intermittent fever to establish the prophylactic influence of trees, when situated about a dwelling, and between it and places known to be malarious. Physicians of the present day, who fail to acquaint themselves with this most attractive volume, miss a rich intellectual feast, and a great amount of useful facts and details not elsewhere presented in the same perspicuous and happy style. Here are gathered the records by many learned and careful observers in various places, of the influence of surroundings, direction of winds, elevation of site, and obstacles interposing in preventing the access of malaria. To this mass of testimony I add my own mite of experience.

In the autumn of 1848, after the subsidence, for the year, of the fevers infesting the region, I took up my residence in a narrow valley, having a stream flowing through it, but subject to interference in its course by ledges of rock, mill-dams and other obstructions. I did not observe any malarial manifestations until August of the following year, when many cases suddenly presented themselves. As an unacclimated person, I would of course be especially prone to an attack, and this was confidently predicted by those who were "to the manner born." Knowing my peril, I adopted the maxims inculcated by the eminent author mentioned; I avoided the night air as much as possible, and when obliged to be out wore a silken handkerchief as an oro-nasal respirator, in the manner pointed out by him. I escaped the disorder, but had ample opportunity to study its phenomena as exhibited in others —several members of a family in given cases being simultaneously prostrated by it. The autumn of 1849 I dwelt adjacent to the same stream, but nearer its source. At this point, by reason of insufficient drainage-fall, and because of obstructions by rocky ledges and fallen trees, its waters spread over an area of several square miles. The submerged territory was lessened by droughts and increased by heavy rains, the rise and fall being intermittent during the autumn. I do not remember using the precautions resorted to the autumn previous, and became a victim to the prevalent baneful influence. I attributed my former immunity to the careful observance of prophylactic measures, and especially to the use of the veil. Though nearer the fen than at my former residence, the fever was not more rife than in that neighborhood. Whether I should have escaped had I used the precautions of the former year I know not: but I am still of the opinion that there is much in "Fences against Malaria" which is entitled to our regard and observance.

Yours truly,

Enos T. Blackwell, M. D.,
Cedarville, N. J.

Knotted Umbilical Cord.

To the Editor.

Sir: The relative scantiness of literature upon the subject of knots in the umbilical cord leads me to report the following cases:

Case 1. Mrs. G., twenty-eight years old,

had had one delivery at term and one abortion previously. Nothing unusual about her labor, except the precipitate termination of both second and third stages. In the cord there two single knots several inches apart. On account of adhesions the knots could not be untied.

Case 2. Mrs. D., thirty-three years old, had had two deliveries at term and one abortion at the fifth month previously. Examination, on August 29, showed that the head was low, in L. O. A. position. The cervical canal freely admitted the finger. The funic souffle was heard, the pulse-rate being 150. Delivery occurred without accident on September 2. The cord passed once around the neck of the child. The total length of the cord was twenty-six inches. At distances of eight and twelve inches respectively from the placental end there were single knots without adhesions; so that they could be untied without difficulty. As the child was born in the same position that it occupied four days before labor, the knots must, in all probability, have antedated the examination. Neither the knots nor the loop of cord around the neck caused any demonstrable interference with the circulation.

Case 3. Mrs. D., thirty-seven years old, had had seven deliveries at term and a miscarriage at the fourth month previously. Menstruation had not occurred for ten calendar months. Examination, on September 10, showed that the child was in L. O. P. position, with a pulse of 140. Labor occurred on September 13, the occiput rotating anteriorly. The vernix caseosa was unusually abundant; the placenta was very friable; the cord had a greenish color and a shrivelled appearance. Exact measurements could not be made, but the cord was short and, being about the child's neck, it had to be cut before delivery could be effected. At two points in the cord, the vessels made loops about one-fourth inch in circumference, supported by a thin process of Wharton's jelly. Although at first sight these off-shoots did not appear to be knots, further examination made it probable that they were the remains of knots formed quite early in gestation, the jelly having accommodated its shape to the general direction of the cord. There is a suspicion of syphilis in this case.

Yours truly,

A. L. Benedict.
86 W. Huron St., Buffalo, N. Y.

Notes and Comments.

Micro-organisms and Amœboid Cells.

In a paper in the *British Medical Journal*, August 30, 1890, Dr. M. Armand Ruffer says:

It is easy to show that the epithelioid cells of infectious granulomata have functions similar to those of the same cells in lymphoid organs. In tubercle, for instance, such cells not only take into their interior the specific bacilli and digest them, as Metschnikoff had noticed, but, according to my observations, such cells absorb and digest the smaller lymphocytes which enter into the formation of the tubercle nodule. In glanders, also, I have seen the same process taking place in the epithelioid cells entering into the formation of the chancre in the Schneiderian membrane of the horse. But there is one disease in which the destructive action of these cells can best be studied, namely, in actino-mycosis. Professor Crookshank, in his researches of this disease in men and animals, described large mono-nucleated cells, which he rightly, in my opinion, compared and regarded as identical with the epithelioid cells of the tubercle. If, instead of examining the centre of each microscopic nodule, which consists of the central mass of hyphen-like bodies lying in a nest of epithelioid cells surrounded by inflammatory material, the periphery of the nodule be examined, a number of epithelioid cells are found, often containing in their interior one, two, three or more—sometimes as many as eight or ten—lymphocytes in various stages of degeneration. They, like the epithelioid cells of tubercle, of glanders, lymphatic glands, spleen, etc., are easily recognized by their large, clear, vesicular, generally single nucleus, and the large amount of vacuolated protoplasm surrounding it.

The power which such cells possess of taking into their interior and destroying pathogenic micro-organisms has already been dwelt on by Metschnikoff. As a rule, however, epithelioid cells are concerned chiefly in the destruction of other cells which have been weakened, or have died, as the result of their struggle with pathogenic parasites. Notice also, that these cells do not pre-exist at the point where the struggle takes place, but that time must elapse—several days in most cases—before such cells are formed.

Of the larger multi-nucleated cells (so-called giant-cells) which are found in certain chronic forms of inflammation, namely, tubercle and actino-mycosis, I have little to say that is new. According to Metschnikoff, such a cell is formed either by karyokinesis (the protoplasm of the cell not dividing) or by the fusion of several epithelioid cells. In any case I agree with Metschnikoff in thinking that, far from a giant-cell being a structure in any way weakened or diseased, it is on the contrary a most active body—in other words, a *fighting* cell. Every one who has successfully isolated one, and has seen its long slender processes often prolonged in the interstices between many groups of cells, cannot doubt that it is an amœboid structure. Its contents, again, show it to be a combatant, for in it are found numbers of tubercle bacilli, in various stages of destruction—a fact already described in masterly fashion by Metschnikoff, whose observations on that point I can only confirm.

I have lately, though quite accidentally, observed one fact which illustrates this destructive function of giant-cells. In the spleen of many animals, more especially of guinea-pigs, the uninucleated epithelioid cells often contain a quantity of pigment, which is really the remainder of red corpuscles destroyed in the interior of these cells. I have lately shown that the number of these cells is greatly increased in certain infective diseases, that is, quarter-evil. In the spleen of tuberculous guinea-pigs, in which the tubercle has invaded that organ, the destruction of red blood corpuscles in the macrophages of the spleen is an extremely active one, but—and this is the most interesting point—the giant-cells of tubercle take an active share in this process, and I show you here two giant cells absolutely crammed with blood-pigment and débris of partially-digested leucocytes—a further proof that giant cells are amœboid, and, like other amœboid structures, have the power of taking into their interior, and digesting, red blood corpuscles, leucocytes and micro-organisms.

Considering, therefore, that the tubercle-nodule consists of a number of extremely active amœboid cells, which all have the power of seizing, destroying and digesting tubercle bacilli, I am of the opinion that the nodule is really a barrier raised up against the invasion of the whole organism by the specific bacilli, and that the processes taking place in the nodule, as long as the anatomical elements composing it are alive, serve a useful purpose.

Lately I have published facts showing that processes going on at the point of inoculation of the virus of quarter-evil are really protective in their nature. I endeavored to show that in this disease, as soon as the virus was introduced subcutaneously, an emigration of leucocytes took place, which, surrounding the virus, prevented the specific bacilli from getting into the system. Moreover, the leucocytes, taking the bacilli into their interior, destroyed and digested them. The conclusions I drew from those experiments were that:

(1) The inflammatory process consecutive to the introduction of the bacilli of quarter-evil under the guinea-pig's skin is a protective process, and serves a useful purpose; and (2) the destruction of micro-organisms at the point of inoculation is carried out entirely by the amœboid cells present in the inflammatory exudation.

More lately still I have brought forward similar facts relating to diphtheria, but, as they have only just been published, I must restrict myself to repeating the conclusions at which I have arrived.

1. The bacilli of diphtheria are present in the most superficial part of the membrane only, that is, in a place where they are well within reach of medicinal agents, an observation not without interest from the point of view of treatment.

2. In the diphtheritic membranes there is an active struggle taking place between the amœboid cells in the membrane and the micro-organisms. In other words, the diphtheritic membrane is a battlefield for amœboid cells and the pathogenic microbes of diphtheria.

3. The reason why the bacilli do not actually penetrate into the tissues is probably that, as soon as they try to do so, they are arrested by the amœboid cells present in the diphtheritic membrane.

Salol for Tonsillitis.

Few diseases are more prevalent in our climate than acute angina. And while attacks of tonsillitis and pharyngitis are not to be classed with the graver affections, the amount of suffering and discomfort they entail often make them objects of serious concern to the practitioner. These inflammations are strictly self-limited, and gene-

rally subside without treatment in from three to seven days. Nevertheless, the means at our command to lessen the annoying dysphagia and other distressing symptoms are not as satisfactory as they might be, especially from the patient's point of view.

Salol has lately received some warm praises as a drug that can be relied upon to favorably influence the course of these affections. Gouguenheim and Capart have pointed out its utility, and in our country Dr. Jonathan Wright, of Brooklyn (*The American Journal of the Medical Sciences*, August, 1890), speaks highly of the remedy. As salol is one of our newer compounds, Dr. Wright's brief synopsis of its properties and action may serve as a reminder here.

It was discovered by Nencki, a Swiss chemist, in 1883, and first used by Sahli in 1886. It is a colorless substance, sold in the shops as a coarse, white crystalline powder. It has a marked aromatic odor, and a faint taste, which is rather agreeable than otherwise. Chemically it consists of salicylic acid in which one atom of hydrogen has been replaced by the phenol group, and contains synthetically forty per cent. of the latter and sixty per cent. of the former. It is a proprietary article, made abroad, and usually sells at four dollars a pound.

It is insoluble in water, but, like the fats, is soluble in alcohol and ether, and is decomposed by sodium bicarbonate. Hence it should not be given in combination with the latter. It forms emulsions easily. Though crystalline in structure, it cannot be reduced to a fine powder, on account of the tendency of its particles to cohere. It has a low melting-point (43° C.).

It is insoluble in the gastric juice, but is readily dissolved in the pancreatic and intestinal secretions, where it is separated into its primary constituents, both of which are readily absorbed and appear in the urine, giving it the olive-green color caused by carbolic acid. In thirty-grain doses it is a powerful antipyretic, but in smaller and frequently repeated doses (five grains every hour) it is not so efficient in this regard. Its odor is very distinctly appreciated in the secretions and in the expired air.

The unique characteristic of salol in being able to pass the gastric juice unchanged, while in the intestines it is decomposed into phenol and salicylic acid, both being antiseptics, has been taken advantage of in treating the summer diarrhœas of children. The rapidity with which these drugs are absorbed, and the promptness with which they appear in the urine, have made it valuable in treating cystitis, pyelitis and gonorrhœa.

It has been used as an antipyretic successfully. But its principal use has been as a substitute for the compounds of salicylic acid in the treatment of rheumatism.

It has proved of service in sciatica and lumbago. The observations on its effects in allaying the pain in rheumatism are interesting in a consideration of its action on the dysphagia of acute throat affections, the time in which it is said to relieve the pain—twenty-four to forty-eight hours—corresponding very closely to the author's experience. Its occasional entire failure is also noted in both cases. The carboluria, which is always present, is the only sign of any phenol poisoning that is noticed, and need consequently give rise to no apprehensions.

In its administration he has never given less than sixty grains daily, nor more than one hundred and twenty, the most frequent dose having been ninety grains for adults. It may be given in powder form or as an emulsion. The most efficient method is to give it in ten-grain doses every two hours during the day.

He has noticed the most marked effect in lacunar tonsillitis, less in catarrhal pharyngitis and least in a well-developed quinsy. For the latter, hot fomentations and free incision are the best remedies, though salol may be given as an adjuvant. This, of course, only applies to cases after the fourth day, before that time the greatest relief being often obtainable by the use of the drug.

Dr. Wright concludes by transcribing Gouguenheim's summary, which he endorses in every particular:

1. Salol acts beneficially in acute anginas of whatever cause.
2. It quiets the pain and dysphagia with the greatest rapidity.
3. In quieting the pain it may shorten the duration of quinsy.
4. It lowers the temperature.
5. In nearly all cases it diminishes the duration of angina.
6. In order to attain these results, the dose should not be less that sixty grains daily.—*Medical Record*, Sept. 6, 1890.

Nature and Treatment of Impetigo.

Dr. Brocq writes from Paris to the *Journal of Cutaneous and Genito-Urinary Dis-*

eases, September, 1890, that Dr. W. Dubreuilh has just published in the *Annales de Dermatologie* an article on impetigo. He has already made known to your readers the views of the French school upon these points. We no longer adopt in Paris the opinion of Professor Hardy that impetigo should enter into the category of eczema. For us impetigo is an affection *sui generis*, definitely characterized by its vesico-pustular aspect, by its evolution, by its auto-inoculability and its non-inoculability to a healthy individual. It sometimes complicates eczema, but it may exist alone and follow its complete evolution as an impetigo without being complicated by an eczematous eruption.

These ideas, long held in honor at the Hôpital St. Louis, have been newly sustained by Dr. Dubreuilh. He believes that the intra-epidermic inoculations of any kind of pus may give rise to impetigo. Still one cannot find in the suppurative focus the origin of this dermatosis; but then its genesis is explained by the fact that we frequently find the *staphylococci pyogenes* upon the surface of the healthy skin, and in the dust which surrounds us. The question of the terrain still remains the most important, since the same causes may act upon many individuals without determining in all eruptions of impetigo. In fine, impetigo appears to the author to be an entity, perfectly determinate from a clinical point of view by its superficial pustule containing a quantity of viscous pus, which dries in thick and honey-like crusts, as well as by its contagiousness, while there is no etiological specificity, it being due simply to an inoculation under certain conditions of pyogenic microbes of whatever origin. He says that we cannot distinguish a contagious impetigo as a special form; there is but one impetigo —the impetigo vulgaris—which is contagious.

In Dr. Dubreuilh's opinion, ecthyma is only an irritated impetigo, inflamed by the sanguineous stasis, by the friction of the clothing, by traumatisms of every sort, and favored by dirt and often by a cachectic state.

The following is the method which he recommends for the treatment of this affection. The capital point is to detach the crusts and prevent their reformation. The first indication may be filled by poultices or by ointments; the second, by applying them frequently and in great abundance, so that the surface of the skin may not be allowed to become dry. Thus he advises that the diseased surface should be smeared twice daily with a layer of the topic sufficiently thick and covered with linen smeared with the same ointment, and retained in position by a suitable bandage. As an ointment he recommends vaseline and lard, each 50 parts; oxide of zinc, 20 parts; salicylic acid, 2 parts; acetate of lead, crystallized, 1 part. Each time the application is renewed it is well to cleanse the diseased surface by gently wiping it rather than by washing, and to lift up the crusts which may have accumulated.

A Medico-Legal View of Painless Labor.

Dr. Brunon recently reported to the *Société de Médecine* of Rouen the case of a primipara whose labor was so nearly painless that she herself mistook it for difficult defecation and would have been delivered in the water-closet if she had not been removed from it. According to the abstract published in *La Normandie médicale*, she felt only lumbar pains and a sense of weight in the rectum, and was not aware of the flow of liquor amnii. The author infers from this case that the discovery of a new-born infant in a water-closet pan does not necessarily raise the presumption of premeditated infanticide.—*New York Medical Journal*, Sept. 6, 1890.

Leprosy in Spain.

Some interesting particulars are given by the British Consul at Cadiz, in his last report, as to the San Lazaro leper hospital, which has been in existence at Seville for over 600 years. The first leper house in Spain was founded at Valencia, in 1067. The San Lazaro Hospital was founded by Ferdinand the Third, when he took Seville from the Moors in 1248. It is situated about a mile to the north of the city. A decree was issued in 1478, confirming previous enactments to the same effect: "That all persons without distinction residing within the Archbishopric of Seville and the Bishopric of Cadiz, denounced and declared lepers, must go to the Hospital de San Lazaro, Seville." This decree was carried out with great rigor. From the reign of Alfonso X, down to the last century, it was the custom for four patients to visit Seville daily on horseback begging,

and as they were not allowed to speak to ordinary persons, they attracted attention by means of boards. In 1854 the hospital was put under the charge of the Diputacion Provincial; the edifice was then little better than a ruin, and contained only 29 patients. In 1864 the building was repaired. The patients, who number on the average from 30 to 36, are looked after by Sisters of Charity. From the official reports it appears that the patients are not all lepers, cases of cancer, "inveterate" syphilis and other diseases being admitted.—*British Medical Journal*, August 30, 1890.

Boroglycerin Cream.

The following preparation is said to be excellent for chapped hands, lips, etc.:

Dissolve one part of boric acid in twenty-four parts of glycerin; add to this solution five parts of lanolin free from water, and seventy parts of vaseline. The preparation may be colored and perfumed.

A Third Ureter Emptying into the Urethra.

The Atlanta *Medical and Surgical Journal*, September, 1890, quotes from the *Monatshefte für Praktische Dermatologie*, that on the 29th of March, 1890, Dr. Desiderius Velits presented to the Medical Society of Budapesth, from the gynecological clinic of Prof. Tauffer, a fourteen-year-old girl who had suffered since birth with dribbling of urine. There was present, on the upper third left side of the large urethra a small opening. A hollow urethral sound directed into this opening upwards and backwards, somewhat to the left, emptied, after a moment, drops of urine. The cystoscopic examination revealed that both ureter openings were normally present in the bladder, and this third canal did not open in the bladder but—as shown by moving the catheter—passed over the posterior wall of the bladder, somewhat on the left side—above and to the left. The bladder was opened through epicystomy, and the opening of this third ureter fastened in the bladder, above the sphincter vesicæ, as follows: By means of the inserted hollow sound, the anterior wall of the abnormal ureter was carried behind and above the left vesical ureter opening, and the canal opened with a slit upon the sound, so that the button of the sound was now visible in the bladder; and at the same time urine dropped in the bladder through the freshly made opening. Then a portion of this ureter, anterior to the opening, was cut out, and cut end was cauterized with the Paquelin cautery. The bladder and abdominal wounds were sutured. Healing occurred without reaction, and about a month after the operation there had been no dripping of urine.

NEWS.

—Dr. David D. Stewart has removed to 1310 Walnut street, Philadelphia.

—Dr. William Y. Howard has removed to 1103 West Broadway, Louisville, Ky.

—The medical schools in Philadelphia began their regular Winter Sessions on October 1, to large classes.

—On September 26, Governor Beaver, of Pennsylvania, appointed Dr. Ellwood N. Corson, of Norristown, a Trustee of the State Lunatic Hospital at that place.

—The incorporators of the Rush Hospital for Consumption, in Philadelphia, met on September 30 and adopted by-laws, and gave the enterprise into the hands of the Board of Trustees appointed by the charter. It is expected that active operations will soon be begun.

—The University of Michigan, in Ann Arbor, has opened its current Winter Session with the largest class in its history. This is to the surprise of the officials, as the required course in the medical department is four years instead of three. Everything points to over a hundred gain for this year.

—In New York, in the case of Dr. McGonegal, charged with causing the death of Annie Goodwin by a criminal operation, the jury, on October 3, returned a verdict of manslaughter in the first degree. Sentence was deferred for a week in order to give opportunity to prove character. The maximum penalty is twenty years in State prison.

—The Philadelphia *Ledger*, October 4, 1890, says Mrs. James Caley, probably the oldest woman in Connecticut, if not in New England, died at Easton, in that State, on Thursday, at the age of 110 years. Her age is said to be verified by the town records of Fairfield, where she was born. Although she had been in feeble health for several years she retained her faculties until death. She distinctly remembered events that occurred 105 years ago.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

A Phosphorized Cerebro-Spinant

(FRELIGH'S TONIC).

FORMULA.

Ten minims of the Tonic contain the equivalents (according to the formulæ of the U. S. P., and Dispensatory) of

Tinct. Nux Strychnos,	1	minim.
" Ignatia Amara,	1	"
" Cinchona,	4	"
" Matricaria,	1	"
" Gentian,	½	"
" Columbo,	½	"
" Phosphorus, C. P.,	1-300	gr.
Aromatics,	2	minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

MAJOR PELVIC TROUBLES TRACEABLE TO MINOR GYNECOLOGY.[1]

BY JOSEPH PRICE, M. D.,
PHILADELPHIA.

With the present popular cry of "conservatism," in reference to operation in cases where it is held that all treatment should be tried previous to real surgical interference, it is worth while asking whether this preliminary treatment should not itself be abandoned in the hands of those who plead most pathetically for it. Their cry is not a scientific plea, but in most instances a *personal bid* for indulgence while they try to accomplish something, without acknowledging on the one hand that there is little or nothing to encourage them in their work, so far as results are concerned; and on the other, that there are abundant proofs from the cases that have come out from under their hands, with one treatment or another, that manifold really major surgical affections arise merely from treatment recognized as orthodox from the standpoint of minor gynecology. So far as my own experience is concerned, I do not hesitate to put minor gynecology in a causal relation with a vast amount of the necessary major pelvic surgery coming under my attention.

First among these causes may be mentioned the Emmet cervical operation. Like many other surgical operations, this, when first explained by its distinguished originator, was done in season and out, by every one, without the least consideration of its contra-indications. Very many minor tears of the cervix, in which a cosmetic effect only is obtained by operation, are made distinctly worse by operative interference. In many cases the pain becomes insufferable, from the lighting up of a dormant or unrecognized pelvic trouble, and operation is required to undo the mischief of an unnecessary cervical closure. This fact has been recognized by Emmet himself, and he has counselled the careful selection of cases in order to escape these disastrous results. It should be set down that where there is preëxisting pelvic disease, even though slight, no cervical operation ought to be tried unless absolutely required by the condition of the patient. Another operation which has met with much approval in many directions, and which some measure of success seems to follow in some cases, is the forcible dilatation of the cervix. It is clear that where there is antecedent inflammation of the pelvic viscera, that is, of the genito-urinary system, such an operation as surgical dilatation of the cervix cannot be free from danger. In order to relieve dysmenorrhœa by this procedure, it must evidently be due to stenosis of the os or cervix. The question here arises, can it be told, in dysmenorrhœa, wherein its causes lie? Sometimes; but not infallibly. The fact is, that in many women where a stenosis would be diagnosticated, there is no difficulty whatever attending the menstrual flux. This being the case, it is evident that a diagnosis cannot be made by simple observation without a careful study of all the symptoms. Again, in many women the causes for this condition are complex. It will not do to lose sight of this, and conclude that because a flexion exists dilatation will remedy menstrual pain. It is to be remembered that if there is coexisting pelvic inflammation dilatation will increase it, and, under certain conditions, cause it if absent. Rapid dilatation of the cervix is a distinct traumatism, and along with it run all the dangers incident to septic absorption that attend any other violent procedure, and where traumatism incident to natural causes is confessed to be the cause

[1] Read before the Philadelphia County Medical Society, September 24, 1890.

of so much subsequent mischief, it ought not to be *expected that operative injury can be harmless*. This conclusion, reached inferentially, has been abundantly confirmed practically on the operative table by much of my later pelvic work. In a number of cases with a history of preceding dilatation, the after-operation has exhibited an inflammatory condition of affairs as complicated as any other in my experience. Some of the dilatations were done with preëxisting disease, which was made worse by this interference, while others were done simply to relieve the dysmenorrhœa, and resulted in the establishment of a complicated surgical disease in which operation was *necessary purely to save life*. All in all, I believe that, judged simply by its remoter effects, the operation of rapid dilatation is a dangerous one, *and results oftener in subsequent harm than in lasting good*. The surgical injury to the cervix is, in many of these cases, more pronounced than the tears of the cervix which it is the intention to remedy by Emmet's operation. In this case there is operation at each horn of the dilemma, and the results are often equally bad at both. Simple closure of the cervix in cases of pelvic disorder, almost certainly exacerbate the symptoms. The necessary inflammatory action set up in the suture tract is transferred along the lymphatic or venous channels to the seat of the earlier inflammation, this is lighted up anew, and goes on in its development until a pelvic peritonitis is kindled or rekindled, which at last entails a major operation. The minor gynecologist, as such, who has no regard for or appreciation of the relation of the commonly advocated general closure of perineal and cervical tears to major surgical complications, cannot but be a great factor in the causation of the same. In Pepper's *System of Medicine*, vol. iv, there is on record a case in which the operator hoped to cure a pelvic inflammation by the derivative effect of a perineal or cervical operation. Needless to say, pelvic operation was afterwards done. Such a cure is no less ridiculous than the so-called "faith" cure, and is certainly more actively harmful.

That the inconsiderate use of the uterine sound has been responsible for much inflammatory pelvic trouble, is scarcely to be disputed. This is not because the sound is of itself a dangerous instrument, but because it is put into the hands of every tyro, as an instrument of diagnosis. If used at all, it should be in the hands of those with whom its application, by reason of their skill, will be exceptional, not usual, and the rule should be, that in the hands of the non-expert it should be forbidden. The more expert and experienced the specialist, the more rarely will the instrument be required. My own rule is, that in cases in which it might at first seem indicated, a little patience and diligence will obviate the necessity of employing it. The indiscriminate use of the sound and electrode, is the most serious MECHANICAL objection to the employment of electricity. Every sitting for the electrical treatment is prefaced by the use of the sound, and followed necessarily by the introduction of an electrode of some form. This is by a class of men who, in the main, have had no *previous gynecological training or education* whatever. In such hands such methods can only be harmful, and we are now reaping the fruits of their work in a class of pelvic operations not surpassed in the complications presented. Along with the sound may be placed the curette in the same category. Dilatation, with curetting of the uterus, have placed to their credit a long *series of major operations*.

Another class of cases coming under this head are those in which there has been a long time during which intra-uterine applications have been made. All the caustics in the catalogue have at one time or another been in favor, as cure-alls, in intra-uterine therapeutics. Nitric acid, chromic acid, nitrate of silver and the rest. For a woman to have undergone a routine treatment with this list, and to have escaped pelvic inflammatory trouble, is little short of a miracle. A careful inquiry into many of the cases coming under my care directly and indirectly, reveals the history that all sorts of minor procedures were tried, only to fail and apparently hasten the necessity for operation. I shall refer to and illustrate these points by the citation of cases in the discussion.

SOLUBILITY OF COMPRESSED TABLETS.—Dieterich advises that to such chemicals as are not readily soluble in water some substance be added that will cause the tablets to disintegrate. For salol, quinine, bismuth, lithium, magnesium carbonate, etc., he suggests sugar. For antifebrin, phenacetin and sulphonal, add about ten to twenty-five per cent. of compound tragacanth powder; for salicylic acid ten per cent. of bicarbonate of sodium.

TINCTURE OF IODINE FOR VOMITING OF PREGNANCY.[1]

BY LLEWELLYN ELIOT, M. D.,
WASHINGTON, D. C.

The treatment of hyperemesis gravidarum is a subject well-nigh thread-bare, and any one having the hardihood to introduce the subject at a meeting such as is the present one is likely to receive little attention. Be that as it may, my success with an agent which is condemned by some writers on materia medica as unfit for internal administration is my excurse for bringing the subject to your attention.

With conception begin the various changes and ills consequent upon the pregnant state, which often serve, in a greater or less degree, to render the woman discontented and miserable. Among these annoyances is reckoned vomiting, amounting frequently to hyperemesis. Since the pregnant woman has been taught that nausea and vomiting are natural sympathetic accompaniments of her condition, many endure their sufferings and privations without consulting their medical adviser, often in the vain hope that the morrow will bring better things. It is in cases where the vomiting becomes excessive that the sufferer yields to persuasion and seeks medical aid. I shall not dwell on the causes, the symptoms, or the prognosis of this phenomenon, as it would occupy too much time and would be without the scope of my title. The purpose of vomiting and nausea will be seen from the following quotations: Playfair says (*System of Midwifery*, p. 146), "It is an old observation that when the sickness of pregnancy is entirely absent other, and generally more distressing, sympathetic derangements are often met with, such as a tendency to syncope." Dr. Radford (*Diseases of Women and Children*, p. 551) has laid especial stress on this point and maintains that under such circumstances women are peculiarly apt to miscarry. Bedford says (*Principles and Practice of Obstetrics*, p. 128), "I do not think there is any fact, as a general fact, better established than that pregnant females, who escape nausea and vomiting during gestation, are *exceedingly apt to miscarry*." He has even administered ipecacuanha to induce these disturbances, so as to be able to carry a patient, who had habitually miscarried, to term (*Ibid.*, foot-note, p. 129). Leishman says (*System of Midwifery*, p. 213), "Midwives have an aphorism that a sick pregnancy is a safe one." Ashwell says (*Practical Treatise of Parturition, etc.*, Ed. 1828, p. 167), "We know not how far vomiting may be beneficial in this state." Bard says (*Compendium of Midwifery*, Ed. 1807, p. 171), "Sickness and vomiting so generally occur during the first months as peculiarly to excite suspicion that they are somehow designed by nature to contribute to the woman's safety." I shall not multiply authorities.

Dismissing those similiar cases which require little attention or treatment, I shall preface the histories of my cases by a reference to the procedures generally practiced. Dewees (*Treatise on Diseases of Females*, p. 209), has "repeatedly found much benefit from the use of the spirit of turpentine three or four times a day in twenty-drop doses," "and where the stomach rejects everything almost as soon as swallowed, I have often known a tablespoonful of clove-tea act most promptly and successfully." He confirms the experience of Denman (*Introduction to Midwifery*, Vol. 1, p. 138, Ed. 1802) with opium, who writes as follows: "In cases of excessive vomiting, opiates are generally given with great advantages. But I have persuaded myself that their habitual or very frequent use is prejudicial to the fetus." Verrier (*Practical Manual of Obstetrics*, p. 151) recommends among other things, Gubler's eupeptic elixir in tablespoonful doses. This has been used successfully at the Hospital of Beaujon. The formula for each dose is disastase, 30 grams; pepsin, pancreatin, each 10 grams. Use any simple elixir to make the required volume. Where the vomiting has become uncontrollable and the woman in a miserable state, he recommends abortion as a means of saving the mother's life.

Copeman's method of dilatation of the os is a treatment very successfully practiced and is only accompanied with danger of abortion when the internal os has been passed. Applications of nitrate of silver have been recommended. Charpentier, writing upon the "Vomiting of Pregnancy" says (*Cyclopedia of Obstetrics and Gynecology*, Vol. 2, p. 42), "that tincture of iodide may be mentioned as an empirical remedy."

Winckel, in the literature of "Persistent

[1] Read at the meeting of the American Association of Obstetricians and Gynecologists, Philadelphia, September, 16, 1890.

Vomiting of Pregnant Women" (*Text-Book of Midwifery*, p. 253), has quoted as follows: "Tincture of Iodine—Eliot, *Medical Record*, New York, 1887, xxxii, 422, (fatal)." How this error in quotation could have occurred, I am at a loss to understand, as the history of the case reads very plainly as follows: "At this juncture she was given five drops of tincture of iodine in a tablespoonful of sweetened water; the effect was magical, for the vomiting ceased almost immediately. To make assurance doubly sure, she was given a second dose in thirty minutes. The labor now progressed rapidly, and at five o'clock, three hours after the first pains, she was delivered of a male child, well developed and healthy. The third stage normal. No bad effects followed the use of the iodine" (*Medical Record*, N. Y., Vol. xxxii, p. 422). To check this uncontrollable or persistent vomiting, abortion has been induced in many cases, but I have never thus far been obliged to resort to it as a means of relief.

M. François Cartier, in an article: "Action de la teinture d'iode contre la vomissement" (*L'Union Médicale*, Vol. xlviii, p. 69), has given with success ten drops in the vomiting of tuberculosis, alcoholic gastritis, pregnancy, fever, etc. Gottschalk (*St. Petersburger Medical Woch.*, in Jour. A. M. A., Vol. xiv, p. 686) recommends menthol, and has used it successfully in a case in which he had previously been compelled to induce labor on account of the vomiting.

I shall briefly describe two cases of vomiting, taken at random from my case book.

Case 1. Mrs. W. H., white, twenty-one years old; last menstruation, April 19, 1887. On May 29 she was suffering with severe vomiting. The usual remedies failing, she was given tincture of iodine in five-drop doses to be repeated in half an hour if necessary, otherwise two or three times a day. Her vomiting ceased after the second dose and was held in abeyance by an occasional dose of the iodine. She went to term and was delivered naturally.

Case 2. Mrs. R. L., white, twenty-eight years old; last menstruation, April 2 to 9, 1887; first seen June 5. Had been suffering from extreme gastritis for two weeks; could retain nothing on the stomach. She was given pepsin, bismuth subnitrate and other remedies without success. Tincture of iodine was then given in five-drop doses and stopped the vomiting with the first dose. The doses were continued at long intervals for a few days and were then given occasionally. She went to term and was delivered naturally.

The successes which have accompanied the administration of the tincture of iodine in the treatment of the vomiting of pregnancy encourage me to impress the subject upon your minds. The compound tincture is a more palatable preparation and would, I think, be equally efficacious, as would also the syrup of hydriodic acid, but I have preferred to continue it in the use of the simple tincture.

PERSISTENT SUPPURATIVE INFLAMMATION OF THE MIDDLE EAR.

BY JAMES M. BROWN, M. D.,

PHYSICIAN IN CHARGE OF THE EAR DISPENSARY OF THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA; OPHTHALMIC AND AURAL SURGEON TO THE WESTERN TEMPORARY HOME.

That suppurative inflammation of the middle ear is not so simple or easily controlled as many, both of the profession and laity, are disposed to think, is now well known. A brief reference to the classified report of the Ear Dispensary of the Hospital of the University of Pennsylvania for the past three years will show that it is a condition frequently existing for many years. Out of a total number of 293 cases there given,

35	had continued	6	months.
35	" "	1	year.
60	" "	3	years.
42	" "	5	"
45	" "	10	"
37	" "	20	"
19	" "	30	"
11	" "	40	"
7	" "	50	"
2	" "	60	"

Thus it will be seen that about seven per cent. of these 293 cases had continued from 40 to 60 years; 19 per cent. from 20 to 40 years; 29 per cent. from 5 to 20 years, and 44 per cent. from an acute stage to 5 years.

Is there any other condition so offensive to both patient and friends and generally so amenable to treatment as this, which would be permitted to continue for such indefinite periods? The self-consciousness of a foul ear, the dread of offending both sense of

smell and sight in others, has deprived the possessor of such of many hours of pleasure, has been a hindrance in life-pursuits, completely changing the intentions or aspirations of its unfortunate victim. I fear too often the profession is the cause of dereliction in treatment of these cases; for it is a story often told the specialist by the patient, after years of uninterrupted suppuration, that the family physician in early childhood said: "Let it alone, as the child grows older he will grow out of it;" and later, when such a delusive hope was not realized: "it has continued so long now it must not be checked or it will break out elsewhere." Led by an ignis fatuus into the "slough of despond," "the last state of that man is worse than the first."

The fact that diseases of the ear received such slight attention in the course of instruction formerly given in our medical halls is the probable cause of their being so little understood, or so lightly regarded, by the general practitioner. It should therefore be a matter of gratulation, and is of no slight import, to be able to note that the more progressive medical schools of to-day have embraced in their curricula both didactic and clinical teaching in this branch. Thus the graduate of to-day should enter the practice of his profession, not only well grounded in the general principles of diseases of the ear, but also with a practical or clinical experience.

It is not, however, to this that I desire to ask attention, but to some of the circumstances which tend to keep up persistent suppuration of the middle ear and its adjacent structures, in spite of apparently well-directed measures to control it. Granting, in a general way, that suppuration means perforation of the tympanic membrane, I may say that the nature of the perforation has in itself a decided influence on the continuation of the discharge. Proper drainage here, as elsewhere, favors subsidence of the inflammatory action and promotes reparatory processes. While it is not anatomically exact, it may be said in a surgical sense that the middle ear is a closed cavity until the inflammatory process ruptures the tympanic membrane. After rupture occurs, drainage is established—defective or sufficient, according to the size and position of the perforation. When this is small or high up in the membrane, it is necessarily imperfect; when the perforation is of insufficient size to favor the outflow of such a fluid as pus, it is only by methods applied through the naso-pharynx—such as swallowing, blowing the nose, etc.—that the cavity is freed of its pus. When the perforation is high up, the pus must collect in the middle-ear cavity until it reaches a depth equal in height to the point of perforation before it can flow outward. These unfavorable forms of perforation not only tend to persistency, but are the cause of secondary morbid changes. The continued saturation of the mucous membrane with pus macerates and destroys its delicate structures, and in the process of repair exuberant granulations are thrown out and may cover the entire surface, or develop into polyps; or the process of maceration, extending deeper, may destroy the periosteum and cause death of the bone. As a result of the presence of polyps, we may have occlusion of the auditory canal or perforation and extension of the inflammatory process. While it is usual in such cases to have violent acute symptoms, it not infrequently happens that the symptoms are of a mild and more chronic form, leading to the belief that the condition is suppurative inflammation of the tympanic cavity only. The delicate periosteum lining the mastoid cells and the antrum, or covering the bony interstices, is destroyed; the bone structure softens and disappears — not so much as sequestrum but rather by a process of disintegration which may continue for years—until, as in two cases under care at the University Hospital during the past year, there is nothing left but an outer shell of mastoid bone.

In the tympanic cavity, long continued suppuration is sometimes caused by a communication of the original trouble to the upper and inner portion of its bony wall, and thus, hidden beyond and above the remnant of membrane, it may, without careful examination, remain for a long time undiscovered. This point is also a favorite seat for polypoid growths, which may not be of sufficient size to reach the perforation, or which may hang down on either side and escape notice.

There is sometimes found, especially when there are complications in what is called the tympanic attic, or where the perforation is in the membrana flaccida, necrosis of one or more of the auditory ossicles. So persistent is the suppuration here, that these cases were formerly considered as incurable. Persistency is sometimes the result of a diseased condition of the upper portion of the

respiratory tract, particularly in the subacute and chronic forms of rhinitis and pharyngitis.

Hypertrophy of the tonsils or of the turbinated bodies, or of the mucous membrane of the naso-pharynx, must be considered as exerting a direct influence on the nutrition of the mucous membrane of adjacent cavities; for it must be remembered that the lining of the middle ear consists of a membrane which performs the double duty of mucous membrane and periosteum, endowed with a highly sensitive structure, richly supplied with both blood-vessels and sensory nerves—the latter derived from the tympanic plexus, whose extensive anastomoses bring it into intimate sympathetic relation with disturbances in remote portions of the system.

In this connection I desire to call particular attention to the unfavorable influence of excessive or perverted sexual indulgence. After very extended and careful clinical observations I am fully persuaded that it is in direct causal relation to the condition under consideration.

In constitutional conditions, such as tuberculosis, scrofula, syphilis, both hereditary and acquired, and diabetes mellitus, the tendency to rapidly destructive chronic suppuration after a usually mild or painless acute stage, is well known. It seems indeed not only that the inherent resisting power of the mucous membranes of persons in these states is deficient, but also that they have great lack of reparatory power, as manifested in the inability to secure gratifying results from treatment. It is true that some cases show a temporary subsidence of the aggravating symptoms, but these recur on the least indiscretion or exposure to undue climatic or meteorological influences. In syphilis the studies of Gradenigo have shown that the specific effect is primarily in the internal ear, and secondarily a suppurative inflammation of the middle ear with proliferation and hyperplasia of the connective tissue, and eventually necrosis—the inflammation and subsequent lesions not differing in any appreciable degree from those in disease of simple origin. Sexton and Burnett, whose opinions have more particular reference to non-suppurative inflammation, maintain that the primary change is in the middle ear. Be this as it may, when suppuration occurs as the result of a specific infection it is of obstinate character and very recurrent. In tuberculosis Moos has found hyperplasia of the tympanic membrane, especially in the cuticular layer with engorged blood-vessels, proliferation and purulent infiltration, which destroyed the membrane and left the handle of the hammer bare, thus tending to produce necrosis of it. Habermann notes the propagation of bacilli through the interstices of the membrana propria, and says: "The great obstacle to recovery is the persistence of a local tuberculous condition, which is an unending source of new inoculations."

Many other co-existing diseases or constitutional conditions to which a retardation of the cure of suppurative ear-disease can be traced, may be noted, such as Potts' disease, anemia, leucocythemia,[1] prolonged nursing, grief, bad food or bad hygienic surroundings, habits of life, such as excessive use of tobacco or alcohol, etc.

The original idea of this paper was to call attention to the causes only, of continued or persistent suppuration of the middle ear; but this study has for its object the cure of these conditions. Passing over the ordinary or routine treatment applicable in general to all simple and uncomplicated suppurative cases, I will briefly describe the methods I have found most effective. The first principle here, as in all surgical procedures, is cleanliness, the removal of all effete material, and procuring as nearly as possible a strictly asceptic condition of the parts. Thorough cleansing of the middle ear can be effected only through a proper opening in the tympanic membrane. If this be insufficient in size, or unfavorable in position for either drainage or cleansing, I invariably resort to surgical procedures at once. To do otherwise is mere temporizing. If the original perforation is in the middle or lower third, my plan is to enlarge it by an incision downward to the periphery of the membrane; if it is in the upper third or in the membrana flaccida alone, I usually enlarge it by an incision directed towards the nearest part of the margin, preferring that the other end of the incision should reach the ossicles. I make also a counter opening in the lower third. The use of an eight or ten per cent. solution of cocaine, applied for five or ten minutes previously, renders these procedures comparatively painless. Then, with the applicator and absorbent

[1] Two cases of ear disease in leucocythemia—one of splenic, the other of lympho-splenic origin—have come under my notice.

cotton, I carefully mop out all secretions. The use of a four per cent. solution of cocaine, applied on pledgets of cotton for a few minutes produces a shrinking and retraction of the thick and irregular edges of the perforation, if it be an old one, and of the hypertrophied or granular mucous membrane of the tympanic cavity, rendering the cleansing process more satisfactory. Where the secretion is tenacious, or inspissated, or caseous, the use of Dobell's solution introduced with Blake's middle-ear syringe is of great service. It must not be used with the force of an injection—for this is what I most strongly condemn — but rather as with a pipette or dropper. The frequent use of the Politzer bag, or of the Valsalvian method, during all these manipulations, is indispensable; though the latter tends to temporary congestion and even bleeding when the mucous membrane is in a state of exuberant granulation.

Finally, after thoroughly drying the cavity, the use of an application to modify the morbid process and to secure asepsis is demanded. Amongst the many remedies used for this double purpose, none has been found so efficient as Listerine, diluted with water to one-fourth its full strength, according to the sensitiveness of the parts. This is applied first by simply mopping the surface or lightly touching it with pledgets of cotton saturated with the solution. It may give rise to sharp pain lasting from a few seconds to one or two minutes, but having a local anæsthetic effect, it soon produces a very agreeable sensation of warmth, and then I apply a similar pledget, allowing it to remain in light contact with the perforated membrane for several hours, where it slowly gives up its antiseptic fluid and absorbs the pus.

I am aware that there will be urged against this method the same objections that are justly made against the use of dry powders, such as boric acid, iodoform, etc., viz., that they confine secretions at the risk of producing secondary disorders. But after an experience of over one thousand applications of this kind, in both simple and complicated cases, I have yet to see the first truly unfavorable symptoms. This may be due in part to the observance of the following precautions: A free outlet is secured by proper perforations in the tympanic membrane; the pledgets used for the Listerine are made narrow and tapering, and of such size as to very loosely fill the external canal; they also rest quite lightly against the membrane. The first applications are permitted to remain only about six hours, with instructions to the patient to remove them sooner on the slightest indication of pain, or feeling of fulness in the middle ear. I can recall only one or two cases where even this has been necessary. Later applications may remain from twelve to twenty-four hours.

I have not, as a rule, found favorable results from the use of caustic or astringent solutions, believing, with Burnett, that they cause swelling of the edges of the perforation and consequent interference with drainage. Corrosive sublimate, zinc, silver, carbolic acid and thymol, I have used in solutions of varying strengths; but they are not all germicides, and many of them prove highly irritating. I have had good results with mild solutions of nitrate of silver, applied at intervals of from twenty-four to forty-eight hours; or with finely-powdered burnt alum: one part, combined with two parts of iodoform, after the formula of Buck—applied after thorough cleansing, so that they may come in direct contact with the diseased structures. I, however, confined their use to cases in which the perforation is extensive, amounting to almost complete destruction of the membrane and where the inner wall of the tympanum is covered with granulation tissue. I have had but limited experience with peroxide of hydrogen, confining its use more particularly to where the remnants of Schrapnell's membrane became inverted and formed sulci or pouches for the retention of pus and débris, as described by Sexton, or where the muscular or ligamentous structures, or perhaps the retracted membrane, formed bands of adhesion across the tympanum with narrow interstices difficult of cleansing. Its effervescing qualities force it into these minute recesses, carrying with it the beneficial aseptic effects of the nascent oxygen.

Enlarging the perforation should always be followed by a thorough exploration of the tympanic cavity, especially that part known as the attic, and also a careful examination of the ossicles. The probe, slightly bent near its extremity, should be passed in all directions; when, if there is denuded bone, it will be discovered and should be very carefully curetted, remembering that it is an extremely thin plate of bone that intervenes between the instrument and the meninges of the brain. If necrosis of the ossicles is discovered they are removed

wholly or in part according to the extent of their involvement; though of course it must not be forgotten that the retention of the stapes in situ is of importance in preserving intact the internal ear and the function of hearing. Proper aseptic treatment is then pursued usually after the manner given. In two cases in which the malleus and incus, together with the membrane, were removed during the early part of last year, a speedy cure resulted, followed in one by re-formation of the membrane which, while it more completely effected a cure by closing an abnormally open cavity, reduced the hearing power from thirteen to seven inches.

Where the disease has extended to the mastoid cavities, pursuing the mild but destructive course alluded to in another part of this paper, heroic measures are needed. In such cases it is proper to make an artificial opening through the external wall posterior to the auricle and, after thoroughly curetting the cavity, to free it of all dead or disintegrating bone, endeavoring under proper antiseptic precautions to stimulate healthy granulations and thus if possible to obliterate the cavity. The two patients before mentioned did not appear for treatment until perforation of the outer bony wall had taken place with probably greater destruction and more unfavorable results than would have occurred if they had been seen earlier, and an artificial opening with proper subsequent treatment had been made. Senn's method of bone implantation might be tried in these excavated mastoids, though difficulties would be encountered—not wholly insurmountable, I trust—in securing the necessary continuous aseptic condition of the part.

Where prolonged suppuration is due to disease of the naso-pharynx, it must receive appropriate treatment, the details of which are not properly within the scope of this paper. Suffice it to say that improper treatment here can of itself be a cause. I have known it to be kept up by the continued use of a nasal douche, self prescribed and unnecessary. Any, or all other conditions or manifestations of disease, both local and general, or their underlying constitutional tendencies, must be thoroughly studied and appropriately recognized in treatment; and, finally, to obtain a well-measured degree of success, there must be taken into proper consideration all that pertains to the health, habits, occupation, temperament and disposition of the individual affected.

NECROSIS OF THE MAXILLARY BONES AFTER MEASLES.

BY JAMES F. McCARTHY, M. D.,

DUBUQUE, IOWA.

On November 27, 1887, I was called to see Peter L., residing with his parents at 2310 Couler Avenue. The boy was eight years old. Family history good. Had three sisters and two brothers all in good health. Twelve hours before I was called, his mother noticed a rash on his face and chest, and I found a mild form of measles fully developed. The diagnosis was made, and I ordered that no medicine be given, but, should complications arise, to advise me when they made their appearance. Three days later I was sent for and informed that the boy had severe pain in his left ear. Upon examining the patient I found the left jaw swelled, somewhat red, and he complained of severe pain in his left ear and jaw. I applied dry hot applications to the jaw and ear, and administered five minims of tincture of opium. The temperature was 103½°, the pulse 140, the respiration 54 per minute; and the boy was constipated. I gave compound laxative powder to relieve the constipation, and applied a jacket poultice of greased flannel covered with oiled silk, as capillary bronchitis was well marked in both lungs. I gave internally quinine in powder, carbonate of ammonia, whiskey and beef tea.

December 1 the temperature was 103°, the pulse 150, the respiration 64, the ear suppurating and the pain relieved. The jaw was larger and more painful.

I noticed the two incisors and the canine tooth of the left upper jaw protruding from their sockets. The patient was very weak and unable to open his mouth over one-half inch. December 2 the condition was the same, and the treatment was continued.

December 3 the temperature was 103°, the pulse 150, the respiration 60. The three mentioned teeth were loose and easily removed. Upon examining the bicuspids, the incisors and canine being previously removed, I found them loose. There was an exceedingly disagreeable odor and very little suppuration. The latter was swallowed, except when syringed out with a bichloride solution 1-2,000. December 4 I removed the remaining teeth in the left upper jaw. December 5 the temperature was 100½°,

the pulse 120, the respiration 38. The patient felt somewhat better. December 6, 7, 8 and 9 the condition continued the same, and the boy took liquid nourishment freely. December 12 the temperature was 99°, the pulse 120, the respiration 28. The face was now very much swollen, the left eye closed and turned towards the nose. The boy could not open his mouth sufficiently to allow a careful examination to be made, but I discovered a large piece of loose bone, and supposed it to be the alveolar process of the upper jaw. I now gave iodide of potassium with tonics. The next day the condition improved.

By December 24 the temperature was 99°, the pulse 120; the boy had no cough and took nourishment well in liquid form; he was still unable to stand. I found all the teeth loose in the left side of the lower jaw except the last bicuspid. December 31 the swelling of face was reduced, and the patient felt stronger.

January 17, with the assistance of Dr. Bigelow, I administered chloroform, and forcibly opened the mouth, grasped the bone with forceps and removed it. The left superior maxillary was removed from the median line to the zygomatic fossa, including all the alveolar process and up to the infra-orbital foramen on the facial surface and to the palate bone on the internal surface, leaving only the orbital surface. The palate bone was left intact. February 6, with the assistance of Dr. Minges, I removed the alveolar process of the left side of the lower jaw, leaving the last bicuspid, although removing a portion of the alveolar process surrounding it.

May 1, 1888. I found the boy with his eye straight, no deformity of face, except that when attempting to laugh or whistle his lips would draw towards the left. The superior maxillary was reproduced and three teeth were making their appearance—one incisior, one canine and one bicuspid. In the lower jaw all the old teeth that were removed are replaced by new ones; the old bicuspid still remaining.

This form of necrosis occurs more frequently in children from three to eight years old, and is a sequel of the eruptive fevers, more particularly scarlet fever. It is more likely to occur at this period of life, when nature makes its greatest demands to supply nutrition for the removal of the temporary and to supply nourishment for the permanent set of teeth. There are cases on record where the bony structures are reproduced (especially the inferior maxillary) but nowhere do I find where teeth have been reproduced in the upper jaw. Nor can I find any account where the superior maxillary is replaced. The most interesting part of this case is the rapid destruction and separation of the parts, the almost complete reproduction of the parts and the absence of any marked deformity.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting, September 24, 1890.

The Vice-President, John B. Roberts, M. D., in the Chair.

Dr. Joseph P. Tunis read a paper on

Rib-Fracture from Muscular Action, with Forty Collected Cases.

In this paper he described and analyzed the histories of forty cases of fracture of the rib from muscular action and gave a summary of his conclusions. He found that of these accidents, more than one-fourth have occurred in individuals of apparently sound constitutions; and the left side has been most often affected, either the middle or anterior third of the rib being the usual position of the fracture. Of forty-nine fractures, only five had occurred above the sixth rib; the great majority had been among the lower six (omitting the twelfth). The exciting causes had been: Coughing, twenty-five; muscular effort, eleven; sneezing, three; and vomiting, one. The determining cause had been the action of the muscles, unless thirty-four observers had been deceived by the testimony of patients who could gain nothing by such deceptions.

Herard reports the youngest example of this accident, in a woman, twenty-two years old. No case has been published younger than this—no doubt on account of the great elasticity of the ribs in youth.

In the forty cases studied by Dr. Tunis, two patients died of some intercurrent affection. The remaining thirty-eight made a complete recovery in the usual time.

More men (twenty-two) had suffered than women (seventeen), and the average age was forty-eight years.

In conclusion, Dr. Tunis said that the difficulty and the doubt which have attended the diagnosis of many of these cases ought to disappear as more and more examples of this accident are reported. Already, by the consent of the majority of surgeons, and by the evidence of accumulated cases, the possibility of rib fracture from muscular action, even in persons of sound constitution, seems sufficiently proven.

Dr. Joseph Price then read a paper on

Minor Gynecology as a Cause of Pelvic Trouble.

(See page 441.)

In the discussion that followed Dr. E. E. Montgomery said: I fully second what Dr. Price has said with regard to the frequency of troubles necessitating major operations which result from the various methods of procedure in minor gynecology. I do not think that any person who has practiced gynecology has not met with cases of inflammatory trouble of the uterus traveling to the ovaries and to the peritoneum, giving rise to conditions which have been described as peri- and para-metritis which have resulted from the use of the uterine sound. When we consider the fact that the uterine sound has been a part of the routine method of examination of many physicians practicing this branch of the profession, it is not surprising that these troubles should so frequently occur. The uterine sound, as has been stated, should not be introduced in any case until the patient has been thoroughly examined and the presence or absence of any inflammatory condition in the uterus or about it has been eliminated.

The practice of Emmet's operation upon cases as soon as they consult a physician for treatment, where a slight laceration is found and the physician at once attributes the symptoms to this lesion and performs the operation, has justly led to its discredit. The operation is undoubtedly one which, in some cases, is of great benefit; it is, however, in properly selected cases. No case in which the presence of other inflammatory conditions has not been eliminated or cured by proper methods is suitable for the operation. One reason, I think, why Emmet's operation has proved so disastrous in many of these cases is the fact that, as the result of sub-involution of the mucous membrane from this lesion, we have an increased amount of secretion which, after narrowing of the cervical canal by the operation, is unable to escape freely; consequently, the uterus becomes dilated to a certain extent, and this favors more rapid extension into the Fallopian tubes and the development of serious trouble. One cause of the extension of inflammatory trouble from the uterus to surrounding parts is insufficient drainage from the cavity of this organ.

Then, again, Dr. Price very justly condemns the use of irritating materials which have been employed in the cavity of the uterus. Many who have proposed agents for the treatment of inflammatory troubles in the cavity of the uterus have seemed to labor under the idea that the only method of curing these inflammatory lesions was by destroying the mucous membrane in which they originated. The application of nitric acid, chromic acid, nitrate of silver in stick, and the like, results in relief by destroying the mucous membrane from which the secretions take place. In this way inflammation may be caused which may extend to the deeper structures of the uterus and to the pelvis. I fully agree with all that the gentleman has said in regard to the importance of care in the treatment of these various classes of cases, to avoid adding to the discomfort and to the crippling of the whole future of the individual who applies for treatment.

Dr. John C. Da Costa said: I am glad to hear Dr. Price speak of the dangers of minor gynecology, but I do not know how we shall get along without it, unless we adopt the rule (which he leads us to infer from his paper is his) that in all these ailments we open the abdomen and remove the tubes and ovaries. I hardly think that Dr. Price is right in attributing the major pelvic troubles to gynecological treatment, for, from the little that he has said, I think that we may infer that the pelvic trouble already existed, and the practitioner made a mistake in treating the uterus rather than the uterine appendages. I am glad to hear him speak in regard to Emmet's operation. I have heard long lists of cases reported with the statement that "all recovered without bad symptoms." That has not been my fate. One of the hardest fights that I have had for a woman's life has been after an operation on the cervix. Many unnecessary operations are done on the cervix. They are often done by men who want to make a record—by men who practice gynecology without knowing much about it. They see a torn cervix, and, without knowing whether

or not the symptoms are due to that, proceed to operate. They do it, also, without properly preparing the patient beforehand. Where a larcerated cervix needs operation, as a rule, it needs previous treatment. If the cervix is put in proper condition, there will not be the same liability to bad results.

There is probably no instrument that is more used in minor gynecology than the dilator, and there is probably no instrument that can be more abused than the dilator. Professor Goodell has reported to this Society many cases in which forcible dilatation has been used with grand results. I have used forcible dilatation in many cases, and have never had any bad results. The reason is that, when I began the study of gynecology, I was taught how to use it properly and not to use it in every case. Take the sharply-bent womb, and all the pessaries made will not straighten it. You must put something inside, either a dilator or a sponge-tent. Again, let the uterus become congested and the mucous membrane swollen, closing the uterine canal and causing dysmenorrhœa. You can cure that case in from two to four treatments by dilatation, while you may treat it by other means for months without doing good. The dilator is a surgical instrument, and one which must be handled carefully. You must know how to do your work before you attempt to use it.

Now, in regard to the use of the sound. I hear gentlemen state that they can outline any uterus without the sound. I have tried that, but have never been able to do it. Take a uterus enlarged, like this sketch, and I defy any one to say in what direction the canal runs. It may be a uterus in the normal position with a fibroid of the posterior wall, or it may be a retroflexed uterus with a fibroid on the anterior wall, or a plastic mass between the uterus and bladder. It behooves us to use the sound carefully. If a man tries to force the sound into the canal, he will certainly do damage. If, however, he will outline the shape of the uterus as well as possible, and then bend the sound to fit as nearly as may be, and then make effort after effort, he can, in the most distorted uterus, get the sound in without damage.

Then, in regard to the curette. These usually have a sharp, cutting edge. Such an instrument is hardly safe for an able practitioner to use, and is not safe at all in the hands of an unskilled person. Where inflammation extends from the uterine cavity to the tubes, after the use of the curette, it is not so much from the instrument as from the man who uses it.

I should be loath to give up intra-uterine applications. I have used them a long time, and, while sometimes pain has been caused, they have never done any serious damage. As Professor Wallace used to say, "Some uteri are sensitive to the slightest touch, and some are as stupid as oxen." When you make an application, you must know the uterus which you are treating. Nitrate of silver used to be a common application, but it is one of the worst that you can make. It will, as a rule, produce cicatricial contraction of the canal. Nitric acid, although so much stronger than nitrate of silver, is not so apt to do this; but nitric acid is rarely required. In a case of fungous granulation, I should not hesitate to scrape out the whole inside of that uterus and make a strong application, and, after watching the patient for a short time, send her home and not expect to have any trouble. This is because I know my cases. I do not do it to every case.

I think that Dr. Price will find that the dangers from minor gynecological operations are more because of want of good, sound judgment in the practitioner, and not so much in the operation itself. I cannot agree that pelvic troubles are always due to these minor operations.

Dr. Joseph Hoffman said: I have put on record in the Obstetrical Society a case where the uterus was perforated by the curette, and this case serves to show that the remarks of Dr. Da Costa enforced the argument which Dr. Price endeavors to bring out, to wit, the danger from the wide-spread use of the uterine sound, the curette and the dilator as advocated by some. I believe that, if we took all the gynecological instruments invented and put them together and multiplied them by ten, we should have no such instrument as gives such bad results as the dilator. It is easy for Dr. Da Costa to claim that he knows when to use it and when not to use it. I think that he overestimates his ability to say whether he has ever done harm by it, for patients rarely come back after they are harmed. I have seen today two patients that had been treated by the curette, and from whom I have removed the appendages. In one case that I know of, the uterus was torn by the dilator, then a sponge-tent was put in and allowed to remain I do not know how long. You know

the rest. In the case in which the uterus was perforated by the curette, the operation was done by a gynecologist of considerable experience. Nevertheless, the uterus was ruptured and peritonitis was brought on and abdominal section was necessary to save life. I have to-day had two other women who were treated by minor gynecology; they were both left very miserable. In one the vagina is much contracted and the pelvic viscera are certainly affected. In one of these cases, especially, electricity was used *ad nauseam*. The history is this: first, dilatation and scraping; then, closure of the perineum; and then, opening of the abdomen. In regard to operations on the cervix and perineum, we are to remember that operation on the perineum is not so apt to cause trouble as operation on the cervix.

What operations on the cervix are necessary? Every cervix with a slight laceration does not require operation. Some of these heal without suture, although traces of the damage may remain. The preparation of the patient often shows that operation is unnecessary—puncture and the ordinary derivitive procedures so reducing the size of the cervix that the laceration almost disappears.

In regard to ulceration of the cervix, I do not believe that there is such a thing, except as the result of bad laceration or specific disease. In laceration the ulceration is only apparent; it is really an erosion due to eversion and hypertrophy.

The curette in some cases seems to be a necessary evil which we cannot do without. I have found it useful in getting rid of putrid débris from a miscarrying uterus, in the early weeks of pregnancy, when the use of the finger is thoroughly clumsy and painful, if not impossible, without previous dilatation with a tent. In the presence of such detention, the use of the tent is not without danger, since, during the period of its presence in the cervical canal, all channel of escape for decomposing material is shut off. I can say that I have had no bad results, that I know of, in the use of the instrument.

As to the use of the sound, its use seems more confined to those who are wedded to the traditions of the instrument than from any *actual* value that can be attached to it. On the other hand, it is capable of doing much harm in the hands of those who need it most, because they know least about it and the parts with which it has to deal.

Dr. William E. Ashton said: The question of the use of the dilator depends upon one or two facts. First, as to the condition of the uterine appendages and their surroundings; and, secondly, properly selected cases. I do not imagine that any one would use the dilator when we have present acute or chronic inflammation of the uterine appendages. I think that any one who has had experience in the use of the uterine dilator would hesitate to employ it except in selected cases. I believe that where we have the pelvis perfectly free from local disease, and in cases where the uterus is strongly anteflexed and perfectly movable, and upon the introduction of the sound we find that there is a point of intense pain at the internal os, we shall find in a certain proportion of cases that good results are obtained from the dilator. It is nonsense to talk about the causes of dysmenorrhœa. It is only a symptom. The vast majority of cases of dysmenorrhœa are cases which have a distinct tubal or ovarian origin. It would be absurd to rapidly dilate in such cases.

In regard to Emmet's operation, I quite agree with Dr. Price in reference to minor gynecological operations dealing most disastrous results in the pelvis. We have to look only at the various clinics and see the recklessness with which various operations are done, to see why we have so many abdominal sections. The reckless use of the sound and of uterine applications are responsible for many of these cases. I hold that the sound should only be used after a diagnosis is made. If the diagnosis is made, of what use then is the sound? In a case like that figured by Dr. Da Costa, I do not care what direction the uterine canal takes. If it is a fibroid, I do not see of what use such knowledge would be.

I cannot understand how any man can use instruments where there are inflammatory conditions around the pelvis, because they are a source of irritation and may light up acute inflammation in chronic cases. It should go on record that the uterine sound should only be used by men who have a thorough knowledge of the pathology of the pelvis and who can appreciate the great danger incident to inflammatory troubles in the pelvis.

I agree with Dr. Price that there are few cases in which Emmet's operation is necessary. I grant that there are cases in which the uterus is in a state of subinvolution, where a plastic operation will bring about the cure, but I do not believe in operating

on the uterus if there is any diseased condition of the appendages. Any manipulation under such circumstances is apt to set up inflammation. Four years ago, I had a case of bad laceration of the cervix in a woman, with pus tubes on both sides. I refused to operate on account of the disease of the appendages. She then went to New York and was operated on by a prominent gynecologist, and died of large abscess, the result of the operation lighting up the old inflammation.

Dr. Da Costa, in answer to Dr. Ashton said: I probably did not make myself clearly understood. I do not want it understood that I would do an operation on the cervix if there was inflammation in the pelvis, such as pus tube or anything else. My teaching is: When there is violent inflammation in the pelvis, not to do any operation on the uterus, and to hesitate to use the sound. The discussion has run off from the original text, and it is for that reason that I make these additional remarks.

Dr. J. M. Baldy said: I think that there is no question in the minds of gynecologists that Emmet's operation is a much-abused operation. I think that it is also true that the vast majority of these ill-advised operations on the cervix are done by men who have no gynecological experience and who know very little about gynecology. I can recall two cases in which I was recently called to operate on the cervix by general practitioners, and by whom I was informed that the lacerations were very bad and that the women were suffering greatly. On examination, the tears proved to be comparatively slight, and needed no interference. There are some cases in which a cervix operation at first sight appears justifiable. These are cases in which a cervix is torn to the vaginal vault. I care not if the cervix be torn on both sides to the vaginal vault, if there is not eversion and erosion or much scar-tissue, there is no reason for operation.

I should be loath to give up forcible dilatation in certain cases. It is not to be done in every case of dysmenorrhœa, for the vast majority of cases of dysmenorrhœa are due to ovarian or tubal disease. I believe that in the vast majority of cases where trouble follows the use of the dilator, there has been pre-existing pelvic trouble. I do not think that a carefully done dilatation in a healthy pelvis will do harm. It is admitted that it does tear uterine tissue, but that this can cause trouble, unless the wound becomes septic, I am not prepared to admit.

The use of the sound in the hands of a doctor is in inverse proportion to his skill. The man who is skilled rarely uses it. In such cases as have been mentioned by Dr. Da Costa, I see no use for the sound. I do not see anything essential that it could tell. I must say that I have not seen a uterus of the exact shape he has figured on the board. In the vast majority of cases I have been able to tell which was fundus and which was tumor. If we are dealing with a fibroid, it makes no difference what wall of the uterus it occupies. I do not suppose that I use the uterine sound once a month.

The curette, I think, is a valuable instrument, but it is abused and used indiscriminately. After abortion, I find it most valuable. In some cases of chronic endometrial disease it is valuable. I believe that it will remove almost all necessity for interuterine treatment. I find such applications rarely called for, except, perhaps, the application of nitric acid or iodine, after the use of the curette. I think that the dull curette is useless. The only rational instrument to use is the sharp curette. I was recently called some seventy miles to see a case where the physician assured me that the uterus contained nothing, as he had twice gone over it thoroughly with the dull curette. I used a sharp curette and removed large masses of placental tissue. The sharp curette can be used with as little danger as any other instrument, if used properly in skilled hands.

Dr. J. M. Fisher said: I am engaged in treating a number of uterine troubles with electricity. Dr. Price has stated that the use of the electrode is fraught with much danger. That the introduction of any instrument into the uterine cavity carries with it a certain risk is not denied, but that the electrode is especially responsible for many of the diseases can certainly be questioned. There are certain diseases of the uterine tissue and lining membrane that can be most effectively treated by properly applied galvanism. I can cite one case in which the use of electricity saved the patient from undergoing a major pelvic operation. A woman, forty-two years of age, had a fibroid uterus with hemorrhages, so that she was confined to bed half the days of the year. At the time that I was called she had been laid up for nine weeks and was exsanguine from loss of blood. She had been treated by two good practitioners, and, failing to

give her relief, operation was proposed and about to be done. I made a positive application of electricity, and, after the first or second application, the hemorrhage was arrested. Four applications, extending over a period of twenty-one days, were made. This was in November and December, 1889. After that she menstruated regularly until May, when she was again seized with hemorrhage. I was out of town, and the bleeding continued three weeks. On my return, I made a positive application of electricity and since then the menstrual discharge has been regular, lasting three or four days.

Dr. C. P. Noble said: I am glad that this matter of uterine sound has been brought up, because I am convinced, as the result of my experience, that the less the uterine sound is used, the better for the patient. In most cases but little information is gained. Recently a case passed through my hands in which the question of pregnancy was mooted. She afterwards fell into other hands, and the sound was passed three inches and the patient was supposed not to be pregnant. She was, however, seven months pregnant, as subsequent events showed. The information given by the sound is often delusive. I, however, cannot see that the simple passage of the sound, provided it be clean and passed through a speculum, with a clean cervix, should set up pelvic inflammation, provided such trouble does not already exist. This, however, is neither here nor there, for I do not see that we need to use the sound in diagnosis. In small uteri it is not needed, because the organ can be outlined bimanually; while in large uteri, where tumors are present, the instrument may not reach the fundus, and so give incorrect information.

I must agree with Dr. Baldy, rather than with the author, in regard to rapid dilatation. I should be loath to give it up. I have never seen harm follow rapid dilatation in any case. This is due to the fact that dilatation has been used in cases in which the disease is limited to the uterus. I agree that it is useless and dangerous to dilate the uterus when tubal disease is present. In uterine disease it is capable of doing a great deal of good. I am quite sure that a certain number of cases of tubal disease are set up by a narrow cervix. The secretions of the uterus cannot gain egress and set up endometritis, and the inflammation travels into the tubes. In these cases, if the cervical is dilated to allow the freer egress of secretions, it will be a positive factor in the prevention of tubal inflammation. In such cases as were mentioned by Dr. Ashton, of acute anteflexion, the dilator does a great deal of good.

In fact, in regard to all these minor measures which have been mentioned to-night, I find them of service, but the fact must be emphasized that they are useful only when the disease is limited to the uterus; and that the uterus should not be operated on, in any way, in the presence of pelvic inflammation, particularly abscess.

Why we should give up the curette I cannot understand. There are many cases of hemorrhage from the uterus due to uterine disease purely, where there is no ovarian or tubal disease. In such cases the use of the curette will permanently control the hemorrhage.

I think that one reason septic troubles follow minor operations is because antiseptic precautions are not observed. I think that is the case with the dilator. If used on the office-table, it is impossible to employ complete antisepsis. If such precautions are used and there is no extra-uterine inflammation present, I do not think that inflammation will follow any of the minor gynecological operations.

Dr. Joseph Price said: I am sorry that the discussion has taken the direction that it has, for it does not give me an opportunity to express myself thoroughly; it does not give me an opportunity of pulling out a number of telegrams; it does not give me an opportunity of calling things by their right names. I have thrown down the gauntlet, and no one has quite taken it up. Some one has spoken of minor gynecological methods. In a recent article a writer prefaces what he has to say by giving details of methods for the treatment of "ordinary gynecological troubles." I do not know what "ordinary" gynecological troubles are. If it means from 9 o'clock to 3 in an office, with a nurse and a Sims's speculum, peeping at cervices and taking ten dollars from each patient, then I understand it. He is the great mischief-doer. He tinkers, dilates, curettes and passes the sound, and in from four to six weeks I get a telegram to come and open the abdomen to save the patient's life; that the woman is leaking; that she has a pulse of 130–140, with a temperature of 104°. This occurs weekly.

A speaker stated that there is no harm in electricity. Three fibroids in that jar have

pus in them as the result of the use of electricity. Of the twenty specimens in that jar removed during August, fifty per cent. followed dilatation, closure of the cervix, the use of the sound and the curette. These specimens have come from four clinics in this city and from ten prominent gynecologists. They all had sections to save life, and all were greatly complicated operations.

In regard to the sound, Dr. Ashton has said all that I am capable of saying. I have not used the instrument for many years. It is a common method of determining the existence of pregnancy, particularly among homœopaths, although not confined to them.

In comparison with the former state of the same subject, we must inquire into the causes which must have been at work during the past few years. This private-office work has a great deal to do with it. Many of these men are simply cervix-feelers and never find anything above it. There may be a mass larger than the uterus to one or both sides which he fails to find. They are not anxious to find them and would not be troubled by them.

The dysmenorrhœa in infantile uterus has nothing to do with the uterus. Pelvic pain in all infantile conditions of the uterus and pelvic viscera is exceedingly common. In these cases dilatation avails nothing. Dr. Baldy says that he uses the sound once a month. I presume that he dilates about once a month. I will consider together drainage of the uterus, referred to by Dr. Noble, and the use of the sound and dilator, referred to by Drs. Baldy and Noble. The sound measures about two lines in diameter, but we will say that it measures only one. I am sure that the drainage is quite sufficient through a canal one line or more in diameter. I find that those who have such a love for dilatation always precede it by the use of the sound. If they use it for drainage the indications are not clear.

Dr. Baldy said: I would ask to what part of my remarks Dr. Price refers. He has entirely misunderstood me. He stated that presumably I dilated for drainage, and that I first pass the sound, which will of itself establish drainage, without the dilator. My remarks were not in regard to dilatation for drainage or anything of the kind. I do not know that I specified what I would dilate for. Time did not admit of my discussing that point. In regard to passing the sound once a month, I do not know that I meant to make that a positive statement. The statement was simply made to illustrate the infrequency with which I used the sound.

Dr. Price said: I thought that I had made that clear. I said that I would call attention to two points—that of drainage, as referred to by Dr. Noble, and the sound and dilator, as referred to by Dr. Baldy.

In regard to closure of the cervix, there are a few cases in which the operation is of importance, but the ordinary method of closing the vaginal surface of the cervix only is very imperfect. This forms a large cuspidor-like cavity or retention sac. I have repeatedly split these up, freshened the cervix and made a perfect cure.

I have thrice this summer been called out of the city to open the abdomen in cases in which dilatation had been performed a short time previous.

Disease of the cavity of the uterus and fungous vegetations are far from common. Many healthy uteri are curetted, and it is thought that granulations are found. If the woman had been let alone, she probably would have conceived. The same is illustrated by a class of cases which I have studied among women locked up in a reformatory. Some twenty or thirty women, who had been living lives of chronic inebriety and lust for three or more years, had none of them conceived. After six months' rest, iron and good diet, the greater number conceived on leaving the institution. In these cases no intra-uterine treatment was employed, and only one examination was made to determine the position of the uterus and its relation to surrounding parts in the pelvis.

As a diagnostic instrument, I do not see why any one should want to use the sound. As a student, I never could see what was gained by the use of the sound; in the hands of the trained or experienced it is not needed, and in the hands of the inexperienced it is dangerous. Too much prominence is placed upon an unhealthy condition of the cavity of the uterus; it does not often exist; it is exceptional.

—Lead may be detected with sodium phosphate according to Bernstein (*Pharm. Zeit.*) in solutions where ammonia or sulphuric acid fail to indicate the element. It is necessary before applying the test to add to the solution a little acetic acid and then to supersaturate it with water of ammonia.

PERISCOPE.

Calcareous Fibro-myoma of the Uterus.

Dr. William Ingalls reports in the *Boston Medical and Surgical Journal*, August 28, 1890, the case of a woman sixty-three years old, married; never pregnant; who had had menopause at or about forty.

The prevailing symptom of her present condition was a comparatively moderate but uncomfortable distention by gas in the intestines, which increased, not very rapidly; but towards the end became very distressful. Treatment was unavailing. There were hours of quiet sleep within each twenty-four; but, for the most part, discomfort and pain overcame her phenomenal patience and pluck. On examining the abdomen twelve hours after death, it was found to be greatly distended. A large quantity of gas escaped when the peritoneum was punctured. Exposure of the intestines presented great distention; color dark; appearance of recent limited peritonitis over descending colon. Several points at various portions of the intestines gave evidence of impending perforations, and at slightest touch, openings took place; and through these issued an immense quantity of nearly black, grumous and foul-smelling fecal matter. Following the intestines down to the rectum, a large substance, hard and rough, was felt, which proved to be lying behind the bladder, between that and the uterus, which was small, hard and nodulated. The hard substance had pinched in a bit of small intestine, a portion of which, above and below, was cut off and removed with the mass. The specimen was a hard, firm mass, having two lobes, the larger the size of a big hen's egg, the smaller the size of a walnut. The two lobes were intimately adherent to each other. The outer surface was rough and irregular, covered with fibrous tissue. At one point a bit of small intestine was attached by a mass of fibrous tissue. The mass, when sawn through, was found to have an outer shell of calcareous matter, and an inner portion made up in part of cheesy material, but in great part of a very tough fibrous material. Microscopically, this was found to be fibrous tissue, with a fatty detritus. The mass was a sub-peritoneal fibro-myoma, which had become detached from the uterus, and had undergone a partial fatty degeneration, and calcification of the outer part, forming a shell.

Anæsthetic Leprosy Following Vaccination.

Dr. Sidney Bourne Swift, Resident Physician at the Leper Settlement at Molokai, in the Sandwich Islands, and Dr. D. W. Montgomery, of California, report in the *Occidental Medical Times*, September, 1890, the following curious case.

Peke, male, Kanaka, æt. 25, parents healthy. Has had two brothers and three sisters—one sister died at the Leper Settlement, a leper of the tubercular type. Peke has been a leper of the anæsthetic type for ten years, seven years of which have been spent at the Leper Settlement. In 1878 he was vaccinated, and about one year after, symptoms of leprosy appeared, and there is now a large anæsthetic scar at the site of this vaccination. He has, during his whole life, associated with lepers. Sixteen months ago he was a fine strapping looking fellow, and was employed as policeman and gravedigger in the hospital at Kalawao. He then left the hospital and lived with a woman named Kalehua, who is now, and has been for the last fifteen or sixteen years, laundress to the hospital. She was declared a leper two years ago. Within the last three months Peke has become pronouncedly ataxic.

A piece of skin was removed from the border of a typical lepra patch on the back about two and one-half inches to the left of the second dorsal vertebra. The border was slightly raised—inside the anæsthesia was complete, outside of it sensation was normal. Going from the border to the centre of the patch, there was a gradual loss of pigment. The border was decidedly not tubercular, consisting only of a slight elevation which extended regularly around the patch. Careful microscopical examination failed to demonstrate the presence of lepra bacilli. The sections were left for two to twenty-four hours in Ziehl-Neelsen's carbol-fuchsin solution, and decolorized either by Lustgarten's method, Gram's method or with a dilute solution of sulphuric acid, and then counter-stained with methyl-blue solution—neither lepra cell nor bacilli could be found. After staining the sections in alum-carmine the raised border was seen to be caused by the products of chronic inflamma-

tion. There were giant-cells surrounded by small round celled infiltration in groups looking very much like the formation of tubercles, but as, after diligent search, no bacilli were found, it was concluded that they were simply the products of chronic inflammation probably non-specific, owing to trophic disturbance following leprous disease of the nerves. A piece of tissue taken out of the anæsthetic vaccination scar was examined, but also with entirely negative results as far as lepra bacilli were concerned. It consisted only of scar tissue.

These results coincide with previous examinations of the skin lesions of the anæsthetic type of leprosy—no lepra bacilli have ever been found in these lesions, although searched for by a large number of competent observers. In this class of cases the disease process is really in the nerves, and the skin lesions are secondary. Prof. Dehio, of Dorpat, finds that even in the first indications of the tubercular type, no bacilli can be found. According to him the tubercle first makes its appearance as a small celled infiltration around the hair follicles and the sebaceous glands; these infiltrations by individual enlargement and by confluence form the complete lepra tubercle, and the bacilli are present only in this stage. If his observations be confirmed, it will furnish a rather strong argument to those who still persist in maintaining that the lepra bacillus is not the cause of leprosy, but a mere after-product.

One of the most interesting points in this case is, that Peak had been vaccinated one year before developing symptoms of leprosy, and that the vaccination scar became anæsthetic. The reporters ask: "Might it not be that with the vaccine virus, the virus of leprosy had also been inoculated?" In this they make a very wide guess, and show themselves far too ready to look upon a *post hoc* as a *propter hoc*. It would be hard to prove that the man *might* not have been inoculated with leprosy; but there is no atom of evidence that he was.

Tsa Tsin—a Chinese Emmenagogue.

The *Druggists' Circular*, August, 1890, says: There is a substance sold in New York under the name of Tsa Tsin, which appears to be composed of the leafy tops of some plant, and its botanical origin is said by its venders to be Rynchosa excavata. Hager states in his *Pharmaceutishen Praxis* that the tsa tsin of a certain German dealer is simply Roman chamomile. A pharmacist of New York states that the article now sold as tsa tsin differs materially in appearance and physiological action from that which he formerly handled. This, he states, he obtained through some European, and that since the death of this person he has been unable to obtain any of the article as it was procured through that source.

Stewart Culin, of Philadelphia, who has made a special study of the Chinese materia medica, informs us that "the drug nearest resembling this in name in the Chinese Herbal is called by the Chinese here tsai tsin (Williams' *Tonic Dictionary*, sai san). This drug has been identified as the *Heteropa asaroides*. It is very little used here and never except in combination with other substances. It does enter into the composition of emmenagogues, of which many kinds are used by the Chinese, nearly all compounds from standard recipes. They are made sometimes in the form of pills and are sometimes taken as a tea. It is possible that the name of the substance referred to is taken from the above and in fact the drug itself may be the same, as I have never compared the two. I do not regard the determination of the botanical origin of the drug as at all certain.

Pyoktanin [Methyl Violet].

The *Deutsche Medizinal Zeitung* for September 4, 1890, contains several interesting communications and abstracts in regard to pyoktanin. Dr. Schubert, of Reinerz, reports most admirable results of the use of solution of pyoktanin (1-500 or 1-1,000) as an antiseptic application to ulcerated wounds. The wounds which he treated were not large ones. Prof. Garrè, of Rübingen, is quoted as speaking against the usefulness of pyoktanin, of which he says that in his experience, while it did no harm it did no particular good in the treatment of fistulous tuberculous processes and in foul wounds and ulcers. Dr. Peterson, of St. Petersburg, concluded that both yellow and violet pyoktanin used as a pencil, or as a powder (two parts to 100 of talc), or in solution (1-100 and 1-2,000), has anti-bacterial properties in infecting wounds and ulcers. It seems to work as well as iodoform,

and has the advantage of being without odor. It has, also, apparently no unpleasant effects. Dr. Peterson says he has used pyoktanin in several hundred cases of chancroid, and for this has entirely abandoned the use of iodoform. In gonorrhœa good results were observed after the use of solutions of strength varying from 1-1,000 to 1-100. Dr. Peterson suggests the use of dilute muriatic acid for washing away the stains on the hands or linen of the operator.

Dr. Kessler, of New York, has recommended pyoktanin which he had used in forty-two cases with remarkable success. He describes in the *Medical Record*, July 5, 1890, the success he has had, and recommends pyoktanin most strongly. Dr. Fessler, of Munich, in the *Münchener Medicinische Wochenschrift*, June 24, 1890, uses pyoktanin in scalp wounds. He uses a solution of 1-1,000.

The various reports indicate that pyoktanin is a valuable antiseptic, notwithstanding the fact that there have been some men who have failed to get the success reported by others.

Treatment of Pulmonary Phthisis.

The *Lancet*, August 30, 1890, says editorially: Koch's views on the treatment of phthisis pulmonalis have received interesting support from the experience of a chemist, Herr Reuter, made public in April last at a full meeting of the Lower Austrian Industrial Union. Koch, it will be remembered, maintained at the Berlin Congress that among the remedies capable of bringing the malady to a standstill the salts of gold and silver are of the greatest value, and that among these the first place must be given to "cyan-gold." Reuter, who, as director of great *fabriques* of metallic wares at home and abroad, paid particular attention to those in which the articles in question were galvanically gilded or silvered, observed that in the latter industry the employés who had consumptive or tubercular symptoms, some indeed who suffered from hemoptysis, found marked relief in their work, and continued to improve so rapidly that in a few weeks their return to health was assured. The favorable impression made on Reuter, as to the curative effects of the gold and silver industry on phthisis, he found confirmed by the testimony of employés of every age in these establishments—men, young and old, who had the well-known symptoms of pulmonary consumption, even at an advanced stage, rapidly getting well as they continued from week to week at work. Further investigations strengthened that impression still more, till he had satisfied himself that for the disease in question a healing virtue resides in the prussic acid generated particularly in those workshops where "cyan-metals" dissolved in "cyan-kalium" are used. Impressed by Koch's views, the Medical Association of Vienna has since bestowed special consideration on Reuter's experiences embodied in the paper read before the Lower Austrian Industrial Union last April, and, while admitting the confirmation given to those views by Reuter, it is of opinion that the honor of priority in discovering the efficacy of gold and silver salts in the treatment of phthisis pulmonalis belongs undoubtedly to the latter.

Pasteur Institute Statistics.

The *Bulletin Médical*, September 3, 1890, reports that one hundred and forty-nine persons were treated in the month of June, [this must be a mistake, as June was reported long ago] 1890, in the Pasteur Institute. Of these, thirty-seven were bitten by animals in which the rabid condition was assumed from experiments made; ninety-two were bitten by animals regarded as rabid from a veterinary examination; twenty were bitten by animals suspected of being rabid. The animals that did the biting were dogs one hundred and thirty-one times; cats thirteen times; horses twice; hogs twice; and mules once.

From this it will be seen not only that does the number of persons expected to have hydrophobia continually increase in the neighborhood of the Pasteur Institute, but also that the lower animals are charged with showing the influence of its teaching. It is a good while since hogs and mules have been credited with having caused hydrophobia, but there is no reason why they should not do it in Paris.

Remedy for Phtheiriasis Pubis.

According to *La Médicine Moderne*, M. Brocq uses a solution of one part of corrosive sublimate in five hundred parts of vinegar as a lotion for destroying crab-lice. It is said that it not only kills the pediculi, but also detaches the nits.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

MEDICAL EXAMINERS AND THE HOMŒOPATHS.

Although we recognize the fact that a number of conscientious medical men regard with fear the establishment of Boards of Medical Examiners in the various States, the attitude of the REPORTER has always been favorable to it. One of the great difficulties in the minds of some of our brethren of the regular part of the profession, is that they dread any sort of recognition of the homœopaths, and it throws an interesting side-light upon this fear to discover that the homœopaths seem to be exercised similarly in regard to association with the regular part of the profession. Wherever attempts have been made to secure the establishment of State Boards of Examiners with the object of driving out quacks, pretenders and frauds, there opposition has been met with naturally from the quacks and frauds, and unfortunately, also, this has been assisted by quite as earnest opposition on the part of homœopaths, eclectics and timid regulars. In a number of States those medical men who were willing, for the sake of protecting the community and of elevating the standard of the profession, to keep in the background certain points upon which they did and do not agree, have succeeded in securing the establishment of Boards of Examiners. In all these States, as the readers of the REPORTER well know, the result has been entirely satisfactory to the best members of the profession, although it has brought out very natural complaints from some upon whom any sort of a medical standard would fit very uncomfortably.

The principles which underlie the establishment of State Boards of Examiners seem to us so fair and reasonable, and the result of their operations, where they have been established, seem to have been so admirable and satisfactory, that it is with great regret we call attention to the position assumed in regard to this matter at its last meeting by the Pennsylvania Homœopathic Medical Society. Just before its adjournment, September 19, 1890, this Society adopted resolutions inimical to the establishment of State Boards of Examiners and proposing instead measures which are thoroughly impracticable. These resolutions are presented in full in another part of this number of the REPORTER, and we call attention to them in order to express the hope that the members of the Homœopathic Society who desire the elevation of the standard of medical education and practice in this State will endeavor to secure more rational action at their next meeting. What was proposed at their last meeting has never been carried out, and never will be carried out. Another thing we would suggest to the members of this Society, and that is, that they cut loose, if they can, from that sect to which so many unprincipled frauds are or pretend to be attached, namely, the so-called eclectics;

for it is very unfortunate that any organization with the slightest claim to respectability should countenance the recognition of these Bedouins of the profession.

We trust that the Homœopathic Society will recognize the spirit which prompts those who—although they totally disagree with them in regard to the principles governing the practice of medicine and, being frank, cannot pretend to approve the position so many of them occupy in being called homœopaths, when they are really no homœopaths—would be very glad to have their co-operation in securing those things which we all believe to be desirable, namely, honesty and intelligence in the practice of our art.

It is the opinion of the REPORTER, after what it believes to be a thorough and kindly study of the whole subject, that very much would be done to improve the standing of the medical profession in Pennsylvania—as in every State—if we were all to agree to the appointment of a State Board of Examiners, leaving the naming of the Board entirely to the Governor. The REPORTER would be willing to run any risks that might be imagined, to any honest set of physicians, under such an arrangement; and we cannot understand the hesitation of those who want to make all sorts of conditions, with the view of protecting what they assume to be the rights of certain sets of practitioners. As a matter of fact the State as a State, and the community as a community, have no interest whatsoever in our discussions in regard to methods of practice. What they want is intelligent, well-educated and honest men who will take care of them when they are sick; and we all lose something by assuming a position in regard to this question which justifies or excuses the community in speaking as though we were trying to increase our own income or to enlarge our own importance. It is a pity that any of us should have so acted and spoken in the past as to warrant the assertion that our societies are nothing but trade unions; and the REPORTER believes that time has come for medical men to agree on some plan for raising the standard of entrance to the grave responsibilities of medical practice in Pennsylvania, so that our fellow-citizens shall be as thoroughly protected against fraud and ignorance as are the citizens of any State in America.

HOW BACTERIA ARE DESTROYED.

With the development of the theory of the bacterial origin of infectious diseases, the question naturally arose as to how recovery takes place and as to the manner in which immunity is conferred. One of the older views was that the disease exhausted the particular tissue or pabulum upon the presence of which its invasion and continuance depended. In accordance with more modern views, it may be held that the micro-organisms to which disease is attributed lose their lives and disappear in various ways. The micro-organisms which gain entrance into the body may die from a deficiency of nourishment, since the normal, living cells and fluids do not furnish a good culture medium.

It has been found that the free fluids of the body exert a directly injurious influence upon micro-organisms, an influence ascribed to the alkaline reaction, to the presence of carbonic acid, and to the albuminates normally present.

Other influences to which importance has been attached in this connection are the retention in the system of products generated by the bacteria themselves, the production of bactericidal matters by the tissues invaded, and the defense set up by the cells in the formation of a wall around the micro-organisms. It is highly probable that phagocytosis, the process by which cells take up and apparently destroy invading bacteria, plays a prominent part in protecting the economy from disease.

In the *Deutsche medicinische Wochenschrift*, July 31, 1890, Dr. Ribbert, of

Bonn, records the results of a study of the occurrence of recovery and of the influences concerned in conferring immunity or protection against disease. As he there states, it is necessary to distinguish between absolute and relative immunity. In case of the first no manifestations of disease appear. In case of the second recovery takes place. Absolute immunity is due to the fact that the bacteria are not able to destroy the structures and thus to provide themselves sustenance, from deficiency of which they die. Not only the cells, but also the circulating albumin in solution possesses inherently, or as a result of previous infection, the faculty of resisting the invasion of bacteria. The resistance to one form of microorganism does not hold good for others, but applies individually to each. Resistance already present may for a time be retained in blood removed from the body. It is the cells, not the soluble constituents, subject to constant changes, which are the active agents and which transmit the acquired property to future generations of cells and circulating albumin. Thus it is the cellular elements which confer immunity.

When relative immunity exists, the bacteria are able to obtain more or less sustenance from the tissues. The greater the resistance of the latter, the more nearly the condition approaches that of absolute insusceptibility. The vegetation of microbes may occasion the production of toxic agents, probably, however, only an increased tissue metamorphosis and associated fever. In this way the fluids of the body become laden with the products of tissue change, which may be considered injurious to the bacteria. As a consequence, the latter die, partly outside of the cells. The increased tissue change is due to the activity of the cells. It is thus conceivable that the destructive influence upon the bacteria is possessed especially by the protoplasm of the cells. In this sense, a varying importance may be attached to phagocytosis. In local affections the colony of leucocytes, besides mechanically obstructing the lymph channels, may also accumulate in the cells the products of locally increased tissue change at the point of infection.

CHOLERA SCARES.

The *Lancet*, August 30, 1890, says in an editorial that it must not be too hard on certain of its daily contemporaries in this dull season, but if they could avoid the subject of cholera it would certainly be well for the community and might not be bad for their own interests. At this season acute gastric and intestinal storms will occur, in spite of, and perhaps largely because of, great atmospheric variations, with the earth temperature about 56° Fahr., that mysterious figure, at which Dr. Ballard has shown such cases may be expected, even in the best regulated communities. But they do not constitute cholera and are not importations from Asia. It adds that the man whose case supplied its contemporaries the week before with material was then convalescent, and another reported case was entirely unrelated to his. It was, in fact, a case of acute gastro-intestinal or dysenteric catarrh, aggravated by errors of diet, in a tuberculous child. These two cases were made to do "scare" duty and scare mischief, and to make many nervous people very unhappy.

Already the REPORTER has noted this scare in London and estimated it at its proper value; and we trust that the comments of the *Lancet* will have some effect upon those lay papers which have added to the popular fear and also upon medical men who may have been too credulous in regard to the reports of cholera cases in this country as well as in Europe.

BLISTERING BY HYPNOTIC SUGGESTION.

In the *Bolnitchnaia Gazeta Botkïna*, Nos. 26, 27 and 28, 1890, p. 650, Dr. Jakov V. Rybalkin, house-physician to St. Mary's Hospital in St. Petersburg, communicates a

striking instance of inducing cutaneous blisters by means of hypnotic suggestion, which affords another proof that hypnotism is an agent of an almost miraculous power. The experiment was performed on a highly hysterical, but otherwise strong and well-nourished house-painter, sixteen years old, who could easily be thrown into a deep somnambulistic state simply by closing his eyelids with the fingers. On February 21, at a meeting of medical men attached to the hospital, the patient was hypnotized in the usual way and told that after awakening he was to shiver with cold and to approach a stove in order to warm himself; on doing so, he was to contract a painful and rather severe burn with consequent swelling, redness and blistering about the middle of the inner aspect of his right forearm. The suggestion was repeated thrice; after which the subject was ordered to awake. He immediately obeyed all the commands given, and that most perfectly. On touching the cold stove he suddenly uttered a loud cry caused by the impression of acute pain inflicted by what he supposed was great heat. On inspection of the suggested spot, the doctors discovered a slight pale swelling encircled with a tender congested areola. The patient, with his limb bandaged, in order to prevent the part being touched by himself or any one else, was put in bed in the meeting's room, but could not sleep on account of a sharp cutting pain about the lesion. At 11.30 P. M. the suggested region was found to be considerably swollen, congested and studded with papular erythema, the adjacent zone, four or five centimeters wide, being exceedingly tender to the touch. At 10 A. M. on the next day, there were found two slightly yellowish semi-translucent blisters, one as large as a nut, the other as large as a pea, and, in addition, a crop of minute vesicles, each of the size of a pin's head. On examination eighteen hours after the experiment, all the blisters proved to have coalesced into a single large one. Two hours later, the latter burst and collapsed. On the sixth day, the dried cuticle was accidentally torn away by the patient himself, which exposed a shiny, dry, red scurf adherent to the burnt surface. The latter healed in due course. On another occasion the experiment on the same patient gave the same results.

This is not the first time these blisters have been produced by hypnotic suggestion, but the case is a confirmation of its predecessors and also of curious effects of expectant attention described years ago in essays like those of Hack Tuke on the influence of the mind upon the body. Results quite as remarkable have been produced without the intervention of hypnosis and these as well as those described above must be taken into account in forming a due estimate of many processes apparently of the most mechanical sort.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

THE BIOGRAPHY OF EPHRAIM McDOWELL, M. D., "THE FATHER OF OVARIOTOMY." By his granddaughter, Mary Young Ridenbaugh. Together with articles relating to ovariatomy, and letters from members of the medical profession in Europe and America. 8vo, pp. xvi, 558. For sale by the Author, P. O. Lock Box No. 372, Philadelphia. Price, $5.00.

The medical profession in all countries will welcome the appearance of a biography of Ephraim McDowell. As the man who first did ovariotomy and who opened the way for those who have followed in the field of abdominal surgery, he has become one of the heroes in medicine, and one of the great benefactors of the race. It is meet that we should know the history of such a man. Owing to the fact that his work was done in a State at that time remote from the centres of civilization, and that for many years he had no biographer, his name and the character of his work were for a time in danger of falling into oblivion.

In the present volume we find a full account of his lineage, life, and associations. He was sprung from the sturdy Scotch-Irish race, of a family of force and prominence, and connected by relationship and association with the leading men of his State. When we know that he received his education in the foremost University of the time, and that his life was passed in an environment suited to develop his talents and his self-reliance, it no longer appears singular that he should have had the wisdom and the strength of character to originate ovariotomy. His claim to the title, "the father of ovariotomy," has been fully demonstrated by the late Dr. S. D. Gross, and is given in an interesting manner by the author.

The book includes several interesting monographs

on ovariotomy, and many eulogistic letters and addresses concerning Dr. McDowell. The profession is to be congratulated that due honor has been paid to McDowell and that his claims to distinction—now happily recognized all over the world—have now been recorded in permanent shape.

RAILWAY SURGERY. A practical work on the special department of railway surgery: for railway surgeons and practitioners in the general practice of surgery. By C. B. Stemen, A. M., M. D., LL. D., Professor of Surgery in the Fort Wayne College of Medicine, etc. With numerous illustrations. 8vo, pp. 315. St. Louis: J. H. Chambers & Co., 1890. Price, $3.00.

The enormous development of railways in this country within the last thirty years has brought with it a corresponding multiplication in the accidents peculiar to railway employés. The larger railway companies have therefore come to employ surgeons to look after their own sick and injured. On January 25, 1882, the first meeting of such surgeons was held in Decatur, Ill., and on June 28, 1888, the National Association of Railway Surgeons was formed in Chicago. The author of the present work is the Secretary of the latter Association.

Dr. Stemen states, in his introduction, that over twenty-five thousand surgeons are now engaged in the special work of railway surgery. Such being the case, there would seem to be no doubt that a book specially devoted to railway surgery would find a warm welcome.

The present volume takes up in successive chapters the transportation of injured railway men, their temporary treatment; shock; the use of anæsthetics; lacerated wounds, fractures, amputations; hemorrhage; excision of joints and bones; concussion and compression of the brain; burns and scalds; color blindness; injuries to hands and feet; railway concussion of the spine; transfusion; aneurism; and, in a final chapter, the method of taking care of the sick and injured on foreign railways.

Dr. Stemen prefers ether as an anæsthetic. There is less of his personal experience in the volume, apart from the report of cases, than one would have expected. But he gives on important questions the views of eminent surgeons, such as Agnew, Ashhurst, Gross and Hamilton; and the railway surgeon who consults its pages will find much pertinent advice in the management of his cases.

THE THROAT AND NOSE, AND THEIR DISEASES. With one hundred and twenty illustrations in color, and two hundred and thirty-five engravings, designed and executed by the author. By Lennox Browne, F. R. C. S. E., Senior Surgeon to the Central London Throat and Ear Hospital, etc. Third Edition, Revised and Enlarged. 8vo, pp. xxii, 716. Philadelphia: Lea Brothers & Co., 1890. Price, $6.50.

Browne's *Diseases of the Throat and Nose*, like Fagge's *Practice of Medicine*, represents years of uninterrupted and exceptional experience in hospital and in private practice. It is pre-eminently a clinical work. As the author stated in the preface to his second edition, it is his intention to tell unreservedly everything he has learned, both in consulting-room and hospital-ward, which is likely to be helpful in the diagnosis and treatment of that class of diseases with which his professional life has been almost exclusively occupied. This personal character of the book prevents it from being exhaustive, but makes it more readable, and gives directness and precision to its teaching. It is not to be inferred from what has been said that Mr. Browne states only his own opinions and practice; he gives a summary of the views of other authorities, but by stating clearly when he agrees and when he differs with others, the reader is not left in doubt as to the author's own practice. This method has great advantages, especially for students of medicine.

It will be noticed that the title of the present edition differs from the last; it is now: "The Throat *and Nose and their* Diseases." The reason for this change can be given best in the author's own language. He says: the "opinion is each day becoming more indisputable that in the condition of the nasal fossæ, which constitute the first avenues of the natural breathway, is to be found the key to a right understanding and successful treatment of the majority of faucial, pharyngeal and laryngeal diseases." The part devoted to diseases of the nose has, therefore, been amplified; but the arrangement of the book remains the same.

As regards the tonsils, he adopts the view that it is their function to manufacture leucocytes which act as scavengers for the clearing away of food débris and the holding in check of micro-organisms in the upper respiratory and alimentary tract. The part devoted to their diseases has been expanded.

The illustrations in color, made from drawings by the author, help very much to enrich the volume. They are clearer and more life-like than those usually given. The wood-cuts, however, also from drawings by the author, could be improved upon. As to the general typographical appearance of the book, it will scarcely add to the deserved reputation of the publishers. The type appears to be worn considerably and the press-work is poor. These criticisms, of course, affect only the appearance of the book, which in itself can be recommended most heartily without qualification.

CORRESPONDENCE.

Treatment of Measles.

To the Editor.

Sir: In hunting for an item this morning, I came across your Editorial in number of January 4, 1890, on measles. I had marked it for review; but as the index was inside, and I did not again see it, it passed out of my memory. It seems to me you could not have seen my paper on that subject—in 1872 I think it was—else you could not have written what you did.

I feel that I ought to review it; for in sixty years of active practice, with hosts of children, I have always, from my first case in practice, kept measles patients cool and urged them to drink freely of cold water; and I have never lost a single case under such treatment, while I have seen the greatest suffering, and know of numerous deaths, under the warm treatment.

Yours truly,
Hiram Corson, M. D.
Conshohocken, Pa.

Cholera Infantum.

To the Editor.

Sir: Enclosed please find a formula that I have been using in cholera infantum during the past summer. I have had a number of extreme cases, and in every one it has proved a decided success.

℞ Tr. iodini . . . . . f℥i
Tr. opii camph. . . . . f℥iss
Pulv. gum. acaciæ . . . . . ℥iii
Syr. simp. . . . . q. s. ut ft. f℥vi

In bad cases I order a teaspoonful every two hours, gradually lengthening the interval of dosage, as the discharge is checked, to three, four, five and six hours. I keep up the dosage for a day or two after the little patient recovers. I allow nothing but sterilized milk with a little lime-water, and occasionally beef-tea as food. I do not allow any water to be given to the patient at all; but allow finely-crushed ice to be given often. I place a linen or flannel bandage around the abdomen, and put a soft slip on the patient, allowing also plenty of fresh air. I have the abdominal muscles and extremities bathed with a little whiskey occasionally.

I have not lost a single case since I have used this formula, where the directions have been strictly and carefully carried out. You will probably see my idea for using iodine. I give you this for what it is worth.

Yours truly,
J. A. Timmens, M. D.
Banner City, Kansas.

Questions and Answers.

[In this department will be published questions on any medical subject by readers of the Reporter, and answers by the Editor or by other readers.]

Dr. D. W. C. Laverty, Middletown, Pa., asks.

1. Is the meat from a cow seven or eight months heavy with calf, from a medical or legal view considered healthy or not?

2. Is there any law prohibiting the killing of meat of that kind for food purposes?

3. Has there been any commission or committee appointed by the State or Governor to prevent the sale of adulterated foods, etc.? If so, who are its members and where is it located?

[1. Such meat is not unwholesome in the ordinary sense of the word; but it is not regarded as a desirable article of food.

2. The killing of cattle during pregnancy is not forbidden by law in Pennsylvania; and the sale of the meat of pregnant cattle is not unlawful.

3. No such Commission has been appointed in Pennsylvania.]

Notes and Comments.

Pennsylvania Homœopaths and the Medical Examiners' Bill.

At the last meeting of the Homœopathic Medical Society of Pennsylvania, September 28, 1890, resolutions were adopted setting forth the belief of the Society that it is the duty of the State to foster all medical advancement, and insure the highest and best medical education by direct supervision of all medical colleges within its boundaries, and that all medical examiners' bills are imperfect, however constituted, and fall far short of what is required, in that their most potent function is to limit the practice of medicine and that they touch the subject for which they are ostensibly put forward only secondarily and possibly quite remotely; and that, for these reasons, the Society is opposed to all medical examiners' bills, unless the State should refuse to assume supervision of college work. The Society pronounced in favor of a bill that no one school or system of medical practice shall have a majority of the members upon such a board.

The resolutions instructed the Legislative Committee of the Society to propose a bill covering the following suggestions: A Board of Education, consisting of one old school, one homœopathic and one eclectic physician, and two laymen.

Its duties shall be to fix the standard of education required for admission to any medical college; to examine any one who may not have reached the required standard and to certify as to his or her standing before he or she can be admitted to any college.

To apply the same test of education to graduates from colleges outside the State, and to certify their standing to any medical college within the State, which shall examine the applicant, and, if found worthy, endorse his diploma for registration.

The Board to have supervision over all medical colleges as to their minimum curriculum, length of time and number of courses of lectures, and the faithfulness of instruction imparted, under such penalty as may be provided.

The Legislative Committee was instructed

to present said bill to the Legislature and to use all diligence in securing its passage and enactment as a law of the Commonwealth.

Carbon for Phthisis.

The Vienna correspondent of the *Medical Press*, September 3, 1890, writes that journal that Julius Pick, of Landskron, Bohemia, again brings forward the carbonic therapeutics as a successful remedy for phthisis. This is a form of treatment that was recognized by Traube in 1860, Zenker in 1886 and accepted by Virchow as rational. Since that time many inquiries have followed up the pathological anatomy, with the view of unravelling the anthracosis. It was found that the coal dust penetrated to the lymphatics in the lung tissue as well as the alveolar cells, blood-vessels and bronchial glands, where it lay quietly without doing any harm, but in other cases brought about inflammatory changes from the irritation. Statistics were collected by Hirt, Merkel and others regarding the health of miners, and the effects of coal dust, which was found to be relatively good.

A table by Hirt gives phthisis as 1.3 per cent. These are striking results, and gave rise to much speculation at the time, some attributing the favorable results to the lamp soot, others to the sulphurous gas. The immunity to phthisis of the North Bohemian miners has always been, and is still, a matter of great surprise.

Koburn and Crocq's results given at the Seventh Congress of Hygiene, were not so favorable, unless in mines where a large amount of sulphurous gas was emitted. This led to an examination of another carbon dust worker, the chimney sweep, and 83.6 per cent. were found healthy; among those who had followed the profession for upwards of ten years the result was 93.6 per cent. healthy. Hirt and Merkel confirmed these figures by repeated examination. This might be termed the ancient history of miners' phthisis, but Julius Pick commenced in 1889 to draw our attention to the freedom of phthisis among the North Bohemian miners who are certainly favored with this immunity. Pick commenced his investigations by inquiring if the alimentary canal had no influence in obtaining this result as the dust would be conveyed with the food and drink thither where it would deposit the contained gas and act as an antiseptic conservative, and now asks the question if it be not rational to expect that an organ long kept under the influence of an antiseptic will strongly resist the colonization or development of any infecting germ or tubercular bacillus, and more so when we find the carbon soot of the lamp distributed along the lymphatic tract and interstitial tissue of the lung commonly attacked by the microbe. How to prove the practicability of this treatment by an artificial production of pulmonary anthracosis without running the risk of an inflammatory result was, to Pick the first difficulty. To overcome this, he commenced with inhalations of soot in a nascent state by means of a spirit lamp burning rectified oil of turpentine. The flame was covered with a glass funnel into which was arranged wood charcoal, while the patient had a tube from this to the mouth for breathing directly. By this arrangement the soot entered the mouth and lungs as in the mines where part was swallowed and taken into the alimentary canal. In another case he prescribed tablets of lamp smoke containing a centigramme.

Twenty-four hours after ten or fifteen inspirations of this apparatus the sputa was found black, and proved that it had entered deep into the alveoli of the lung. With this apparatus he has administered the fuligo inhalation without the least inconvenience or annoyance to the patient for five or six weeks twice a day. Fuligo is a wide term if not defined. Pick understands this to be the soot from a chimney where wood is burned, but to get quit of all remaining organic remains he subjects the raw material to a kind of roasting process, which might properly be termed *fuligo depurata*, a black light powder having no effect on the tubercular process of the lung, which it does not irritate, and seemingly has no marked utility beyond the theoretical presumption of a disinfectant. This was the result of his first experiment. The next step was to have this fuligo depurata saturated with a gas taken from coal as well as wood which he terms *fuligo empyrheumatica*, which is also easily borne when depurated.

Medical Examiners of North Carolina.

The annual session of the Board of Medical Examiners of North Carolina was held May 24–29, 1890. The Board consists of seven practitioners elected by the State

Medical Society, each of whom conducts the examination of candidates in one of the seven grand divisions of medical science. That this Board is doing effective work in aid of the elevation of the standard of medical education may be inferred from the fact that of a total of 72 candidates at the examination for 1890 only 46 met the requirements and were licensed, and of a total of 398 applicants before this Board for the six years ending with 1890, *one hundred and six* failed to pass. This will prove interesting to undergraduates who slur their college work, and may awaken them to the fact that State supervision of medical education is so rapidly extending that in the very near future only strict compliance with requirements that, in most colleges, are still too easy, will enable them to find a place in the profession.—*Memphis Medical Monthly*, September, 1890.

Resection of the Liver.

The Paris correspondent of the *Lancet*, August 23, 1890, reports that, at a recent meeting of the Academy of Medicine, M. Terrillon recorded the case of a woman, aged fifty-three, who was admitted under his care at the Salpêtrière suffering from a painful and voluminous swelling in the hepatic region. There was a history of four years' duration. An exploratory puncture was made into the swelling, and a few grams of fluid resembling that of hydatid cysts drawn off. As, however, the tumor diminished little or nothing after the puncture, laparotomy was performed on April 1, the abdomen being opened by an incision running parallel with the false ribs of the right side. A portion of the liver about the size of two fists was drawn outside, and was found to be riddled with innumerable small hydatid cysts. Some of them were already empty, but as the tumor had hardly at all diminished in size, and was continuous by means of a broad base with the liver substance, it was resolved to resect it. As, however, a formidable hemorrhage was to be feared, an elastic band was placed round the base of the growth, and thus an artificial pedicle was constituted. The tumor so held by the elastic ligature was in this way separated from the body of the organ and fixed outside the abdominal cavity. Seven days were then allowed to elapse to give time for the usual adhesions to organize and shut out the peritoneal cavity. At the end of this time the now gangrenous swelling was removed, together with the ligature. The floor of the existing wound was of course formed by sphacelated liver tissue, but securely shut off from the peritoneal cavity by the adhesions which formed. Within six weeks the wound had completely cicatrized over, and now the patient, whom long suffering had reduced to a skeleton, was regaining her usual strength and weight, and leading her ordinary life.

Effect of Extirpation of Pancreas and Cœliac Plexus.

The *Therapeutic Gazette*, August, 1890, says:

We have on two previous occasions referred to the results obtained by Dr. Lépine as to the influence of the pancreas on the destruction of sugar in the organism. The drift of his views appears to be substantiated by numerous papers which have recently appeared, which point to the almost invariable production of diabetes mellitus after extirpation of the pancreas. Thus Von Mering (*Zeitschrift für Klinische Medicin*, Band. xvi, Heft 5 and 6) found that after extirpation of the pancreas, a genuine diabetes is produced in dogs, corresponding to the severest form of this disease in man. Grape-sugar was excreted in large amounts, the appetite was abnormally great, polyuria was present, and, in spite of abundant feeding, progressive loss of weight and feebleness were invariably noted. Together with these symptoms, grape-sugar, acetone, aceto-acetic acid and oxybutyric acid were present in the urine, while there was increase of the sugar in the blood and decrease of the glycogen of the various tissues of the body.

Dominicis (*Centralblatt für Klinische Medicin*, June 7, 1890) has likewise produced permanent diabetes after extirpation of the pancreas, and he believes that disturbance of the digestive functions, brought about by the extirpation of the pancreas, leads to an alteration of the tissue-changes, which result in the production of diabetes. This is, however, a mere hypothesis, which the author does not attempt to prove, and which is by no means as probable as the one suggested by Lépine and supported by Von Mering and Minkowski, which points to a specific function of the pancreas by which destruction of sugar is produced. Thus, Von Mering and Minkowski have found that if an animal is made diabetic by

extirpation of the pancreas and fed with a definite quantity of grape-sugar, the whole of the grape-sugar is excreted in the urine, while if but a part of the pancreas be left, no diabetes is produced.

On the other hand, they state that these results are directly due to the removal of the pancreas and the prevention of the exercise of this specific function, and not to injury of adjacent parts, such as the solar plexus; thus Lustig, quoted in the *Medical Chronicle* for July, 1890, succeeded in removing the cœliac plexus from dogs and rabbits, and, although there was in some cases a temporary glycosuria, permanent diabetes was never produced.

This result was also confirmed by Peiper (*Medical Chronicle*, July, 1890). He never noted the production of diabetes insipidus, and only transient glycosuria in certain cases. Peiper's results are, therefore, opposed to the view that diabetes insipidus depends on the functional derangement of the cœliac plexus, and they also show that diabetes mellitus, following extirpation of the pancreas, is not attributable to injury of this plexus.

Numbers at the Berlin Medical Congress.

The *Münchener Med. Wochenschrift*, August 19, 1890, contains some interesting information about the attendance at the recent Berlin Medical Congress, and how it was distributed. The whole number of members at the conclusion of the Congress was 5,737, of participants 143, and of women 1,376. Of the members, Berlin furnished 1,166; Germany (exclusive of Berlin), 1,752; Austria-Hungary, 262; Great Britain and Ireland, 358; Netherlands, 112; Belgium, 62; Luxemburg, 12; France, 179; Switzerland, 67; Italy, 146; Monaco, 1; Spain, 41; Portugal, 5; Sweden, 108; Norway, 57; Denmark, 139; Russia, 429; Turkey, 12; Greece, 75; Roumania, 32; Servia, 2; Bulgaria, 5; United States, 658; Canada, 24; Brazil, 12; Chili, 14; Mexico, 7; the rest of America, 30; Egypt, 8; the rest of Africa, 6; China, 2; Japan, 22; East Indies, 2; Dutch East Indies, 2; Australia, 7. Of participants Germany claims 97, other countries 46. The number of medical women who took part in the Congress was 14.

It will be noticed from these figures that America sent 745 members, and that the United States alone had a larger number of representatives than any other country except Germany.

Urine of Opium Eaters.

A statement has gone the round of the medical press, to some extent, that tincture of the chloride of iron added to the urine of an opium habitué will give a blue tint, are evidence of the presence of morphia.

Dr. Mattison, of Brooklyn, whose experience makes authoritative what he says on the subject, says that this statement is not true.

Remedies for Neuralgia.

Writing to the *Provincial Medical Journal* regarding the use of new synthetic remedies, Dr. T. P. Thomson states that antifebrin is infinitely a more effectual pain-reliever than antipyrin, the dose is small, and it is not very expensive. Three or four grains in a little brandy or whiskey, and then a little water added to this mixture, is the best way to give it. Repeat in four hours if necessary. Dr. Thomson has never witnessed any bad, depressing effect from the employment of antifebrin. In neuralgia of the head it gives sure and speedy relief. In any given case of nerve pain where one might suspect a weak or fatty heart phenacetin is to be preferred to antifebrin, but it does not seem to act quite so surely as the latter. Phenacetin in seven or eight-grain doses every four hours is a safe and effectual remedy in all neuralgias, be they in the head, back, or any other part of the body. Exalgine he has also found useful, and quite corroborates Professor Fraser's statements regarding its efficacy.—*Chemist and Druggist*, September 13, 1890.

Atropamine.

O. Hesse, says, in the *Druggists' Circular*, October, 1890, that "Atropamine" is the name given by him to an alkaloid which he has found in belladonna root, and which it sometimes contains in not inconsiderable quantity. At ordinary temperatures this is a colorless, tolerably firm, glossy mass, but at 60° C. is quite fluid. It is precipitated out of its salts by ammonia, potassi, or soda solution in the form of an oily liquid. It is readily soluble in alcohol, ether and chloro-

form, and its formula is $C_{17}H_{21}NO_2$. It differs from atropine, hyoscyamine and hyoscine in containing one molecule less of water, but it has on the other hand the same composition as pure belladonna, and also a similar form. It differs from the latter, however, in that it forms very fine crystalline haloid salts, by means of which peculiarity it can be separated notably from belladonnine, but also from all the known alkaloids of the atropæ and allied plants.

Cholera.

Surgeon J. H. Tull Walsh gives in the *Indian Medical Gazette*, July, 1890, the results of the use of salol in the treatment of cholera. By studying his statistics it seems clear that a miscellaneous treatment, with stimulants and astringents, gives better results than the salol treatment. There is, however, reason to believe that the cholera was of a milder type in 1889 than during the early part of 1890, which would in some measure account for the difference in the percentage of deaths. He does not attempt to discuss the general question of the treatment of cholera as he is of the opinion that after the algid stage is reached recovery depends in some way on the vitality of the patient and is generally independent of drugs.

Universal and perfect sanitation should, Dr. Walsh thinks, be the only end and aim of those who desire to see the mortality from cholera lessened.

The Rush Hospital.

At a meeting of the Board of Trustees of the Rush Hospital for the Treatment of Consumption, in Philadelphia, held October 6, the following officers were elected: Hon. William N. Ashman, President; Mr. William C. Bullitt, Vice-President; Mr. Joseph de F. Junkin, Secretary; Mr. Nathaniel E. Janney, Treasurer.

Medical Staff—Visiting Physicians: Thos. J. Mays, M. D., Charles W. Dulles, M. D., Lawrence F. Flick, M. D., J. P. Crozer Griffith, M. D.; Laryngologist, Harrison Allen, M. D.; Ophthalmologist, Edward Jackson, M. D.; Otologist, B. Alexander Randall, M. D.; Surgeon, Henry R. Wharton, M. D.; Pathologist, John Guiteras, M. D.

Consulting Physicians— Alfred Stillé, M. D., J. M. DaCosta, M. D., James Tyson, M. D., Roland G. Curtin, M. D.

NEWS.

—Dr. Charles E. Toothaker, a well-known homœopathic physician, died in Philadelphia, October 5, aged 54 years.

—Dr. Wetherill, Secretary of the Pennsylvania State Lunacy Board, has detected three more cases of improper home confinement of lunatics.

—At Wills Hospital, Philadelphia, Dr. Frank Fisher, Dr. S. D. Risley, Dr. Charles A. Oliver and Dr. Edward Jackson have been elected surgeons.

—It was reported from Madrid, October 12, that the cholera epidemic continued at Barcelona; and that a special hospital had been erected there for the sufferers.

—A fine gymnasium, for the use of the patients, was opened with appropriate celebration at the Friends' Asylum for the Insane, Frankford, Philadelphia, October 7, 1890.

—Dr. C. C. Vanderbeck, of San Francisco—and formerly of Philadelphia—has recently returned from a trip to Europe and has opened a sanitarium at 216 Leavenworth street.

—James M. Doherty, the insane lover of Mary Anderson-Navarro, shot and killed the Assistant Superintendent, Dr. Lloyd, of the Kings County Insane Asylum, at Flatbush, N. Y., October 9.

—On September 15, M. Ernest Hardy died in Paris. He was a thorough and trustworthy investigator of chemical and pharmacological questions, and was the first to isolate pilocarpine from jaborandi.

—Last May a druggist of Grenoble, France, substituted naphthalin for β naphthol in a prescription. The substitution was detected, the druggist was prosecuted and convicted and sentenced to a fine of 500 francs and the imprisonment prescribed by law.

—At the meeting of the Philadelphia Baptist Association, October 8, it was resolved to appoint a committee to consult all the churches and by circular ask for their opinion on the subject of the establishment of a Baptist Hospital; also, to receive conditional pledges.

—Among the features which medical men will find of special interest in the November number of *Harper's Magazine* is a poem, "The Quaker Lady," written by Dr. S. Weir Mitchell, and adorned with seventeen quaint illustrations from drawings by Howard Pyle.

FAIRCHILD'S

PANCREATIC TABLETS.

Afford a convenient, effective, and elegant means of administering the ferments of the pancreas.

These tablets can be given at any interval prior or subsequent to the ingestion of food, at the discretion of the physician, without entailing inconvenience to the patient.

In cases of intestinal indigestion, what can be a more rational practice than the introduction of the pancreatic ferments at the time when the gastric digestion is spent, and no obstacle is offered to their passage into the intestinal tract?

Pancreatic ferments bear no dependence upon an alkaline reaction. They are exceedingly active in neutral solutions and are not rendered inert by a merely acid reaction. It is, therefore, only at the height of *normal* gastric acidity that the pancreatic ferments may be theoretically held to be inoperative in the stomach. The ferments of the pancreas—known to digest rapidly every form of food, starches, fats, beef, milk, fibrin, etc., have proven useful as remedies, *per se*, notwithstanding the prejudice of theoretical views and conclusions based upon experiments under conditions purely artificial and differing in important respects from those in which their employment is indicated.

BURN BRAE

A PRIVATE HOSPITAL

--FOR--

MENTAL and NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

EXTENSIVE AND BEAUTIFUL GROUNDS, affording perfect privacy and pleasing variety. House and surroundings unusually attractive and cheerful. Heat, light and ventilation perfect.

A PLEASANT, SAFE AND HEALTHFUL HOME,

With constant professional supervision. Music, games, open-air amusements, boating, etc., are provided for patients.

THE OLDEST INSTITUTION OF THE KIND IN THE UNITED STATES.

Both sexes received. A limited number of opium habitues admitted. Pleasant companions for female patients.

LOCATED A FEW MILES WEST OF PHILADELPHIA,

At Primos Station, on the Philadelphia and Media Railroad, from Broad Street Station, Philadelphia, Pa.

RESULT OF THE REMOVAL OF A UTERINE FIBROID.—UMBILICAL HERNIA. — CANCEROUS DEGENERATION OF UTERINE MUCOUS MEMBRANE.[1]

BY E. E. MONTGOMERY, M. D.,

PROFESSOR OF GYNECOLOGY, MEDICO-CHIRURGICAL COLLEGE, OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL.

Result of Removal of Uterine Fibroid.

Gentlemen: I operated upon this woman four weeks ago for uterine fibroid. She gave a history of a fall in 1884, since which she has suffered with menorrhagia, and when admitted to the hospital had an exceedingly offensive discharge. When examined the growth was found to protrude itself through the cervix, so that the latter was dilated to the extent of two and one-half inches. This condition might have been produced by one of two things: a fibroid or an inversion of the uterus. Inversion may result from malignant disease, such as sarcoma, or as the result of labor, where premature traction upon the cord, in an attempt to deliver the placenta in a relaxed uterus, may cause it to turn inside out; or, again, inversion may result from traction of a fibroid situated near the fundus. In the examination of this patient, however, finding that the sound passed an equal distance all round, and that there was no indication of a depression of the fundus, I arrived at the conclusion that I had to deal with a fibroid tumor. Further examination also disclosed that the vitality of the tumor was seriously injured from the pressure to which its base had been subjected in the dilatation of the os, and that it was undergoing decomposition. For a few days prior to the operation she had had an elevation of temperature varying from 101° to 103°, which was undoubtedly caused by systemic absorption of poisonous material from this decomposing mass. The first two days after the operation the temperature continued at 103.2°, since which it has rapidly come down to normal. The patient has recovered without any hemorrhage or any unpleasant symptoms.

There are different methods of procedure in the removal of these masses; such as by the use of the spoon-curette, the wire ecraseur, the galvanic cautery wire, twisting the pedicle or cutting through it with scissors. It is important, in whatever procedure is used, to make certain that the whole of the tumor is removed; as any remaining portion will suffer from want of nutrition, will undergo sphacelus and will endanger the life of the individual from septic conditions. This removal, it seems to me, can be best accomplished, where the base of the tumor is not too large, by twisting its pedicle; for this purpose a strong pair of Volsella forceps is necessary.

Umbilical Hernia.

This patient presents an additional condition of clinical interest which you will observe as I expose the abdomen. You see an enlargement upon the abdominal wall at the umbilicus, which increases with coughing, with straining or when the woman assumes an upright position, and which may be partially obliterated by pressure upon it. This is what is known as an umbilical hernia, and as the mass cannot be entirely obliterated or returned into the abdominal cavity, it is evident that a portion of the omentum or knuckle of intestine has become glued fast to the edges of the opening, forming

[1] Delivered at the Philadelphia Hospital.

what is known as an irreducible hernia. You will ask what can be done for the relief of such a patient? If the hernia were readily reducible, so that the whole of the intestine and the other contents of the hernial cavity could be returned, the patient might be able to live comfortably by wearing a truss. In this patient, however, with a portion of the hernia protruding, the feasibility of wearing such an instrument is impracticable, and the only certain and permanent relief of the condition will be an operation in which the peritoneal cavity shall be opened, the intestinal adhesion separated and the protruded portion returned to the abdominal cavity. The edges of the abdominal wall should be dissected so that the muscle and aponurosis are exposed. These should be brought together by sutures and the patient, for a length of time after her recovery, should wear a bandage to support the abdomen and to relieve it from pressure.

A hernia of this character sometimes becomes strangulated. When this occurs, the proper method of procedure would be to relax the abdominal muscles by the position of the body and limbs, and to exercise judicious taxis with a view to the return of the imprisoned viscus. This may be attempted also under the influence of an anæsthetic, by which the muscular relaxation will still be more effective. Should the measures fail, an operation should be resorted to rather than to continue the exercise of external pressure.

These hernia sometimes attain a very large size. A case of the kind came under my notice some years ago in which the protrusion had been with such force as to tear the peritoneum and permit the intestine to dissect up the superficial fascia. Increased adhesions had to be broken up before the parts could be returned into the abdominal cavity.

Cancerous Degeneration of the Uterus.

This woman is sixty-three years old. Her health has been remarkably good until this trouble, and there is no family history of any malignant disease. She has never been pregnant. For about a year she has had an ichorous, fetid, and sometimes bloody discharge. The uterus is enlarged and the cervix is elongated. The introduction of the sound into the cavity is immediately followed by a discharge of bloody and sanious liquid. It is my purpose this morning to draw down the cervix, and, by the use of the curette, to endeavor to obtain some portions of this tissue which we can subject to the microscope to confirm the suspicion I have of the presence of malignant disease. The age of the patient and the character of the discharge are such as to impress us of the probability of the disease being malignant. In order to determine the condition of the uterine cavity, I dilate the cervix, after which I find the sound passes in a distance between four and five inches. The curette is now used, and, judging from the specimens brought forth, I have no hesitation in saying the disease is one of a malignant character. These masses will be subjected to the microscope, after which we will decide farther as to what shall be done. This case presents opportunities of rather unusual interest. In the first place, the body of the uterus is the part which seems involved. This occurs in only about two per cent. of the cases in which the uterus is the seat of malignant disease. In the second place, the patient gives no history of ever having been pregnant. Malignant disease is rare in women who have not borne children. Now, as to the treatment of this patient; the only plan of treatment which offers even a shadow of a chance of successful removal of the disease would be extirpation of the uterus. You can readily see that the application of strong destructive agents within the cavity of the uterus, where its evacuation or drainage would be attended with considerable difficulty, would be a less desirable method of procedure. I have no hesitancy in going still farther and saying that, in the light of the present developments in regard to the treatment of cancer of the uterus, when the disease is limited to the uterus, whatever portion of it may be involved, the removal of the organ is absolutely indicated.

—Chloral and antipyrin are known to liquify when brought into contact. L. Reuter, in a German journal, reports that, allowing this syrupy liquid to stand several days, colorless and tasteless crystals (presumably "tri-chloraldehyde-phenyl-dimethyl-pyrazolon") will form, which are therapeutically inactive, and devoid of the characteristic properties of the original ingredients.

IMPROVED HYPODERMIC SYRINGE.

BY JOHN. J. THOMAS, M. D.,
YOUNGSTOWN, OHIO.

In the MEDICAL AND SURGICAL REPORTER, September 28, 1889, I described a new method of administering hypodermic injections. Through the courtesy of a reader of the REPORTER, I discovered that as long ago as 1876, Dr. Edgar Holder, of Newark, N. J., devised a syringe upon the same general principle as the one I had supposed to be entirely original with myself. The matter of their manufacture and sale seems never to have been pushed; the extreme simplicity of the device probably proving a bar to its general introduction. As far as can be learned, only one firm of instrument manufacturers made and handled the article. Another year's experience with the simple apparatus, already described in the REPORTER, adds greatly to my satisfaction with it. I have suffered none of the annoyances of a broken syringe, dry plunger or lost washer. The operation of giving a hypodermic injection I can perform with greater quickness and thoroughness than when using the usual form of syringe. The risk of the formation of abscess is much lessened; for the syringe I am about to again describe is as nearly aseptic as can be.

Take the rubber or bulbous portion of an ordinary medicine dropper, using care to select one of some strength and firmness. Insert into its open end the proximate extremity of a hypodermic needle. The fitting is not expected to be close, but can easily be rendered air tight by a few turns of thread or, preferably, a fine rubber band —Faber's No. 10 is strong enough. Now compress the bulb to flatness to expel the air, and dip the needle-point into some water, release the pressure upon the bulb and it fills with water in the space of twenty-five or thirty seconds. Now by pressure discharge the water into a teaspoon, add your tablet, make the solution and draw it up again into the bulb, and you are ready for injecting. Pinch up a fold of the skin in the ordinary manner, thrust in the needle and deliver the injection by firm pressure upon the bulb, holding it transversely to the tips of the fingers. The first filling of the bulb and discharging into a spoon is merely to measure the exact capacity of the bulb and to leave no space for air; though the admixture of a minute quantity of air would not be in the least degree harmful, unless injected into a vein. Practically, no air enters; and an objection upon this ground will speedily disappear under a fair test.

The method which I have now employed for a year and a half is, of course, crude, and the instrument far from as nearly perfect as it is capable of being made. A well-known instrument maker, of Philadelphia, is about to manufacture a syringe upon the principle in question. The bulbs will be of two sizes—fifteen and thirty minims. The idea of a screw fitting between the bulb and needle will be abandoned as unnecessary. The needle will be made with a rounded extremity precisely like the glass tubular portion of the medicine dropper, and over this the open extremity of the bulb will fit tightly. A small glass or porcelain dish or cup will be a part of the outfit of exactly the same capacity as the bulb; so that the solution can be made without any preliminary measuring. The bulbs will be made strongly and of the best quality of rubber. They should fill in ten seconds or less. With the injector carried in my buggy-case I can readily be prepared to give an injection within the short space of two minutes. This includes the fastening of the needle and the twice filling of the bulb. Surely, this is sufficiently speedy, but by the help of the instrument maker the time can be greatly lessened. For my part, even if the instrument manufacturers fail to perfect the idea, I have parted company with the ordinary hypodermic syringe. Mine cost fifty-five cents each and give every satisfaction. Others cost from two to three dollars each and are soon out of order. My experience can be made that of any practitioner who will take an interest in the matter, and who will not allow his own lack of skill in its use to lead him into condemnation of the method.

Nothing can be more satisfactory than the operation of this method of giving injections where whiskey or fluid extract of ergot is to be administered. The determination to inflict upon the readers of the REPORTER this second article upon the subject arose upon the recent occasion of a case of placenta prævia, where the operation of version had just been performed under ether anæsthesia.

The patient could afford no further loss of blood, and I desired instant uterine contraction and expulsion of the placenta. Two injections, of twenty-eight minims each, of fluid extract of ergot were quickly given—a pretty large dose; but my object was attained. The arm was pretty sore for two or three days, but no abscess resulted. The uterus contracted firmly, and the patient ultimately made a good recovery. The pulse ran at the rate of a hundred and twenty for forty-eight hours after delivery, showing that not much more blood could have been spared. As the case approached its termination I reflected upon the probable need of the hypodermic use of ergot or whiskey before the finish, and took comfort in the assurance that my syringe was in good order, notwithstanding the fact that it had not been used for many months.

I have four or five or more of these syringes; one that I keep at my home, in my emergency case, for use when walking short distances at night, one or two in my buggy case, and two in my obstetric bag. In fact, by this method one can own as many syringes as he possesses needles; so little more than the needle being required. Said Dr. John B. Roberts, the well-known Philadelphia surgeon and Professor of Surgery in the Women's Medical College, in a conversation held at Atlantic City last spring: "I have so frequently been annoyed at finding my hypodermic syringe out of condition for immediate use. Your idea gives me the means of giving an injection if I have but a needle and a medicine dropper." The same gentleman gives his unqualified endorsement to all my claims in regard to the practical utility of the instrument, and suggests that it be named the "aseptic" injector.

The objection may be made that twenty-eight drops, the capacity of the average bulb of a medicine dropper, is too large a quantity of fluid for an ordinary injection, and that a smaller quantity of fluid will be absorbed more rapidly. We are not certain that twenty-eight minims will be any slower in being absorbed than five or ten. I have not detected any appreciable difference myself. Still, if this objection be a valid one, it applies only to the unperfected method thus far employed by myself. The bulbs can be made of any capacity, smaller or greater than that of the nipple of a medicine dropper. I propose that each case contain two or three bulbs of different sizes, the needle fitting to either one or another.

Instrument makers with whom I have had correspondence approve of the idea, and make promises of carrying it out, but are slow in doing so. The reason probably lies in the fact that the bulb injector would have to be sold at a much lower price than the ordinary syringe, and that it would be durable and never require repairing. Nevertheless, as above stated, an enterprising manufacturer will soon place them on the market.

Now, to sum up; the following are the claims made for the crude apparatus in use by myself: 1. It is simpler in construction than the ordinary syringe; hence more reliable, as it never gets out of order. There need be no leakage. It works as well after one or two months of non-use as if used daily. 2. Its cheapness; the cost being about one-third that of the usual instrument, when provided with two needles. 3. Its effectiveness; it accomplishes all that any other contrivance designed for the same purpose will accomplish, with the single exception of being used as a means of injecting ether. Contact with the latter soon destroys india rubber. 4. It affords a means of rendering the delivery of a hypodermic injection in an aseptic manner. The bulbs are very easily cleaned and easily kept clean. The likelihood of the occurrence of abscess from anything introduced from without is reduced to a minimum.

Improvement and perfection at the hands of the instrument maker will only emphasize the claim made for the device in question. As for myself, as before stated, I have no further use for the method of giving injections ordinarily employed. The plan above described gives equal and abundant satisfaction to both physician and patient.

CATARRH.[1]

BY ERNEST M. LYON, M. D.,
NEWARK, N. J.

Catarrh in its many relations, is a disease so frequently calling for the consideration of every physician, and, one upon the successful treatment of which so much often depends, that a few words bearing upon the matter may not be out of place, especially in view of our experience of the past winter. Broadly considered catarrh may be defined as a diseased condition whose prominent char-

[1] Read before the Practitioners' Club.

acteristic is a discharge or flow from a mucous surface, and for purposes of classification, it may be divided into two great divisions: acute and chronic. Acute catarrh may be further divided into specific and non-specific.

The object of this paper is to draw your attention to the importance of considering catarrh, not simply in the light of a symptom, as is often done, but more as an essential fever, and of treating it as such.

The conditions necessary for the production of a catarrh are first, a mucous membrane; second, some irritating substance or sudden change of temperature; and, third, as a resultant of these or of similar causes, the presence in and around the muciparous follicles of an excess of blood stimulating them to secretion. The gravity of the case depends upon the initial force of the irritation, the situation of the congested part and the success of the means employed to relieve it.

The pathological changes occurring in a case of acute catarrh are interesting. First the congestion, which, if it be severe, distends the capillary circulation to an enormous extent; the contiguous parts are engorged with blood; the circulation through the affected part becomes slower, and, in proportion to the looseness of the tissues, the tumefaction greater. Then Nature attempts to cure this condition by instituting the characteristic flow of mucus with the view of depleting the blood-vessels; this may prove successful, and if so, there is a spontaneous recovery as in a common cold, but if not successful, the congestion goes on accompanied by more or less of fever, until there supervenes a condition of vaso-motor paralysis, the capillaries remaining full, the mucous membrane puffy and sodden and covered with a constant coating of mucus from the relaxed follicles. The disease is then said to have become chronic.

The clinical history of catarrh varies considerably with the location of the attack. When confined to the throat and nose, there is usually frontal headache, suffusion of the conjunctiva, difficulty in breathing through the nose, sneezing and a sense of suffocation, combined with general malaise and some fever. As the disease progresses downwards, the constitutional disturbance becomes more marked, and the symptoms of a corresponding gravity; and if the lungs are reached we may have a profound disarrangement of the physiological functions and often death. It is here in the lungs that catarrh most often gives an exhibition of its possibilities when the inflammation involves a large surface. The lungs, with their innumerable small tubes lined with a continuous mucous membrane, offer a field in which the disease may display its powers upon a grand scale. The fever increases in intensity; cough becomes a prominent and distressing symptom; respiration becomes difficult and accompanied by a sense of oppression. These symptoms subside after a time, either spontaneously or as the result of proper treatment, and are followed by expectoration of mucus and muco-pus; and the attack is over, to result either in complete recovery or in the chronic form of the disease. A severer form is where the inflammatory products so occlude the smaller bronchioles, that, while the exit of air contained in the air-cells is permitted, ingress of fresh air is not. This results in collapse of the cells with inflammatory adhesion, prolonging the case indefinitely and often, especially in children, deciding the balance between life and death.

Gastro-intestinal catarrh may be either general or local, and the symptoms will vary accordingly. It may be general in the sense of involving the whole digestive tract, from the stomach to the anus—as, for instance, in sporadic cholera; or it may be local, as involving some one part as the stomach or cæcum. In the class of general gastro-intestinal catarrh I am inclined to catalogue, not only such diseases as sporadic cholera, but also remittent and typhoid fevers; and, while ascribing the two latter to specific causes I still entertain the opinion that they are both essentially catarrhal diseases. The past winter with its epidemic of catarrhal fever has been the means of convincing many practitioners of the constant presence in the atmosphere of a morbific principle that only needs favorable conditions of temperature, moisture, etc., to manifest itself in an epidemic. The whole history of this disease goes to show that it has recurred at various periods from time immemorial whenever the conditions were favorable, and that it is capable of attacking any or all parts of the body either at once or seriatim. Such a history as this can belong only to a disease having some special microbe or other analogous means of propagation; and the time may come when all catarrhs outside of those due to the action of cold or local irritants, can be traced to the special poison of this disease.

Gastric catarrh, when occurring in the adult, most often comes under the physician's notice in the chronic form, and is usually the result of repeated attacks of acute or especially subacute, gastritis, commonly recognized as dyspepsia by the laity; and it forms one of the most intractable of all diseases to permanently cure, owing to the fact that the physician has the patient's bad habits of eating and drinking to contend with. The acute form is usually the result of the ingestion of indigestible or irritating substances, or of excess in the use of alcoholics, and may prove dangerous to life. The nervous condition known as delirium tremens is nearly always preceded by acute gastric catarrh, which in its turn makes a profound impression upon the sympathetic nervous system. At all events, there is no better way to treat this condition than to direct a part of one's efforts towards reducing the gastric irritation.

Gastric catarrh occurring in infantile life is one of the most common of all affections and also one of the most troublesome. It occurs mainly in bottle-fed infants, and is the cause of much ill health and imperfect nutrition. Children affected with it vomit a large part of their food, and experience a great deal of pain, which causes wakefulness and interferes greatly with sleep. The excessive secretion of mucus interferes with the proper contact of the food with the coats of the stomach (without which there can be no perfect secretion from the peptic glands), and also renders the contents of the stomach more prone to fermentation and decomposition, thus filling the stomach with gas, to the great distress of the infant. When acute gastric catarrh is associated with the same condition in the intestines—as it sometimes is in the adult, and very frequently is in young children—it becomes a serious matter for the patient, and calls for our best efforts, especially when it invades the rectum as in dysentery, or when the vermiform appendix is involved.

Acute catarrh of the genito-urinary tract may be best considered by division into specific and non-specific, of which the former is by far the most frequent and troublesome. Non-specific catarrh in this locality is usually due to the presence of some foreign substance, either in the kidneys, the bladder, the uterus or the urethra, such as gravel, calculus, pessaries or sounds; and it is generally relieved by removal of the irritating substance. Specific catarrh, on the contrary, is due to introduction of the poisonous virus of syphilis, gonorrhœa or chancroid; and their effects may be felt not only locally, but also in parts remote from the seat of the original inflammation. The injudicious handling of a chancroidal ulcer, and the subsequent introduction of the finger into the eye or mouth, has been the means of dimming the lustre of many a bright eye, and of carrying contagion to innocent people. This is also true of gonorrhœa. How many women there are who are barren because of the introduction of gonorrhœal virus into the vagina, that has worked its way upward into the womb, with the result of setting up there an inflammatory catarrh, contact with which would kill the average spermatozoön in short order. This devastating effect of gonorrhœal poison, is also true of the bladder in both sexes; and the inflammation may even reach the uterus, through them the kidneys, while from the uterus it may penetrate to the ovaries through the Fallopian tubes. The chronic diseases of the genito-urinary apparatus are the most intractable and their treatment is hopeless in a large class of cases, particularly those of the uterus and bladder.

Catarrh of the eye and ear will not be discussed in this paper, that being left for some of our specialists.

The list of catarrhal affections fills a large place in the catalogue of diseases calling for the attention of the average physician, and their treatment varies with their location, intensity and cause. Clinically considered, acute catarrh calls for treatment as a disease, and chronic catarrh as a diseased condition. The prime factors in the treatment of catarrh, wherever found and due to whatever cause, are: First, to remove the cause at once if possible. This can be done if it be local, by removal of calculi, pessaries, etc. Second, as soon as possible after the attack has begun we should endeavor to limit the amount of blood in the affected part and give it physiological rest. Third, we must restore the tone of the mucous membrane. In this we can learn a great deal from Nature, who endeavors to cure the disease by institution of the catarrhal flux; and this should serve as a hint for us to do likewise. Acute catarrh of the bronchial mucous membrane, if sufficiently severe to cause much fever, calls for prompt measures of relief. The first and best thing to do, is to produce profuse diaphoresis; and to this end we should use warm or hot foot baths, and give hot drinks containing a

small amount of alcohol, and one of the new antipyretics, of which I prefer antifebrin. After using successively the prominent members of this family of drugs, and especially antifebrin, of which I have administered, since January 1, some thousands of grains, it has proven in my experience the safest and most useful, being devoid of all danger if used with any sort of moderation. The diaphoresis produced by its use is prompt, the fever is always lowered, and often the patient goes quietly to sleep. After the sweat, a large warm poultice of flaxseed and camphor, with mustard mixed into it, should envelop the chest, both back and front if necessary, and this should be covered with oiled silk. An anodyne, such as Dover's powder, should be given; and in nine cases out of ten the disease will be so modified that its succeeding history will not be at all severe, provided we have been called early enough. There has been a great deal said in relation to the use of poultices. Provided they are properly made and applied, they are among the most valuable of the means at our command to relieve this disease and cannot be approached for effectiveness by cotton batting, so much in favor by our homœopathic brethren.

Among drugs, the iodide of potassium stands at the head. It should be given in full doses and as frequently as the stomach will bear it, and it may be given to saturation without danger. This drug possesses the power to promote in some way the flow of mucus, probably by stimulation of the glandular substance; and its use should be continued as long as the fever lasts and a day or two longer, when it should be succeeded by the muriate of ammonia and cod-liver oil for another period. If, in spite of our efforts, the disease becomes chronic, the treatment should become astringent and stimulating; and for this purpose the balsamic remedies are useful, especially eucalyptus and chequen, together with quinine and strychnine.

Gastro-intestinal catarrh should be treated upon the same general principles as the foregoing. When we are called to a patient whose symptoms point to the digestive tract as the seat of disease, it is good practice in almost all cases to empty the stomach and bowels with a purge as soon as possible; and, provided it can be taken, that much-maligned old-fashioned remedy, castor-oil, answers the purpose better than any other. It seems to work better than any other cathartic in intestinal catarrh, almost a specific, in fact. The next important consideration is diet; and the best diet in many cases, for some hours at least, is nothing at all. Give the stomach and bowels as nearly physiological rest as possible—a sort of masterly inactivity as it were. This gives the liver an opportunity to exercise its depurative functions and to rid itself of all superfluous blood—a very important consideration at times, and there is often great disturbance of the biliary function due to catarrh of the duodenum and ductus communis: a condition which favors resorption of bile and consequent jaundice. It is exactly this condition of things that precedes continued fever; and, in my opinion, these same fevers are essentially catarrhal and depend for their continuance upon a prolongation of the original catarrhal inflammation of the intestinal mucous membrane in just the same manner that bronchial catarrh is sometimes prolonged by extension. Should the fever become continuous, the use of quinine is indicated, and it should be given freely throughout the attack and continued into convalescence, occasionally giving it to cinchonism, say once in three or four days, to guard against malarial complications. The use of antipyretics is indicated here, and they should be given whenever the temperature rises to or above 103°, and preferably at night, and they should be continued in decreasing doses until the fever subsides and becomes extinct for twenty-four hours. An important point is the diet; this should be always fluid and should consist of milk, barley gruel, etc. Considerable alcohol, in combination with food, may be taken with benefit. The subnitrate of bismuth, given in fifteen to twenty-grain doses every two hours, is a valuable drug, and may be used with benefit and without danger for long periods. Should the bowels become sensitive, warm poultices, covered with oiled silk, are useful and at times exert a favorable influence upon the fever. This was the case with my own boy and with many others. Enough morphine should be given to allay pain and sleeplessness and to restrain too frequent stools. Should the opposite condition, of constipation, prevail, large enemata of plain warm water are often of extraordinary benefit. Sometimes they are retained for hours without discomfort, to be followed by a natural stool, very rarely, however, of as large a quantity as the injection, part of the water being absorbed.

These patients are benefited by large enemata daily as a part of the treatment. In the declining stage of the disease mineral acids, pepsin and port wine are indicated.

Genito-urinary catarrh is so often the result of venereal causes that its treatment demands a separate paper and will not be discussed here.

SIX SUCCESSFUL OPERATIONS FOR BILIARY CALCULI.

BY B. CURTIS MILLER, M. D.,

LEXINGTON, KY.

Case 1. Mrs. S. A. W.; 44 years old; married, and the mother of seven children; was six weeks pregnant at the time of this operation, after which she went to full term and was delivered of a healthy male child. I was called to see her by my friend Dr. R. S. Henry, of Charleston, W. Va. She was a large, muscular woman, weighing probably 160 pounds, and while she was a little sallow in the face she did not present the appearance of a person suffering from any organic disease of a serious nature. The symptoms, as complained of most and described by the patient, were pain and soreness at various times in the region of the liver and stomach. About once every two weeks this pain was more severe and extended into the hypochondriac region and around to the back in the region of the right kidney. The pain at times was very severe under the right scapula; afterwards it was followed by a rigor and accompanied by excessive vomiting and extensive constitutional disturbance. These paroxysms usually lasted from one to two hours. The woman stated that her appetite had been impaired only during the past two months. She was generally constipated, and her feces were light in color. These symptoms had developed about one year previous to the examination, and had been treated by a number of physicians without obtaining any benefit from the administration of medicines. The abdominal walls were very thick and the muscles quite rigid; and no action from the bowels had taken place during the past three or four days. This condition of the patient prevented a satisfactory examination of the abdominal contents; but I was enabled to make out an oval abnormal growth occupying the right hypochondriac region. It had a slight movement from side to side and was quite tender to the touch. The tumor seemed to be about the size of the two fists. The patient was advised to return home (with the promise that we would see her in a few days) with instructions to take an active purgative the day previous to our arrival. At this stage of our examination we thought it a case of sarcoma of the kidney.

On our arrival at her house, her condition being more favorable for an examination, as a result of the thorough evacuation of the bowel by the action of the salts administered as we had advised, we could now make out very distinctly a distended gall-bladder, which could be readily moved in any direction excepting downwards. The line of enlargement was in a diagonal course from the normal situation of the gall-bladder towards the umbilicus. Dulness existed over the entire growth. The shape was that of a pear.

The abdomen was opened December 5, 1887, with the assistance of Drs. Henry and Mitchel, and a gall-bladder containing 204 stones and one and one-half pints of pus was found. All of them were removed through the two-inch incision in the gall-bladder and abdominal walls. The edges of the gall-bladder were now carefully stitched with continuous sutures to the edges of the parietal wound. In this way the gall-bladder was securely fastened to the abdominal opening, thus preventing the bile from entering the abdominal cavity. I next placed four stitches in the parietal wound, in order to close it around the drainage-tube, which was introduced into the gall-bladder at the lower portion of the incision. This tube was of soft rubber, and remained in the wound for a period of ten days, at which time it was removed and the opening was closed by granulation in a few days. The four stitches which were placed last were removed about five days in advance of the drainage-tube. The dressing consisted only of absorbent cotton, held in place by two or three adhesive strips.

The patient bore the operation well and I left in a few minutes after the dressing was applied, and did not see her for six months, at which time she was enjoying excellent health. I was informed by Dr. Mitchel, her family physician, that her temperature did not rise above 100° during the whole time of her convalescence. This case was included in my year's report of 1889, in which I re-

ported seventy-five cases of abdominal section without a death. (See *American Journal of Obstetrics and Disease of Women and Children*, Vol. 22, No. 7, 1889. Case 66.) This is one of six cases in which I have operated for stone in the gall-bladder and the results in all of the others have been as favorable as here above described.

The remaining five cases may be briefly described as follows:

Case 2. Mrs. W. W. L., 42 years old, applied to me July 4, 1888, complaining of pain in the region of the liver. She was considerably jaundiced, and anemic to a marked degree. The pain in the right hypochondriac was paroxysmal, occurring every three or four days, and continuing for ten or twelve hours. Operation July 7, 1888, and convalescence in three weeks. The calculus in this case was single and weighed 240 grains. My assistants in this case were Drs. S. F. Thomas and E. W. Clarke, of Charleston, W. Va.

Case 3. Mrs. A. M., 28 years old. Operation February 1, 1889. She complained of severe pain in the region of the liver, and was greatly reduced in flesh. Recovery was complete after operation and the patient regained her usual flesh. My assistant in this case was Dr. F. L. Harrison, of Cleveland, Ohio. The contents of the gall-bladder consisted of 240 small calculi and about eight ounces of pus.

Case 4. Mrs. H. L. R. had been in poor health for several years, but did not suffer much pain until one year previous to the operation, since which time she has had a severe gnawing pain in the region of the liver radiating up to the right shoulder, and followed by excessive vomiting and prostration. This operation was performed April 16, 1888, assisted by Dr. Hamilton, of Baltimore, Md. One interesting point in this case was the fact that the gall-bladder had become very firmly adherent to the abdominal wall, and I allowed the adhesions to remain intact after cutting through the parietal walls, and did not think it necessary to put any suture in, as in former cases. The external wound was simply brought together with three or four stitches, after inserting a drainage-tube. The contents of gall-bladder consisted of three stones weighing in the aggregate one and three-quarter ounces. One stone was quite firmly imbedded in the walls of the gall-bladder, and forcible removal of it caused considerable hemorrhage which continued for several days and was only checked by means of injections of a solution of tannic acid into the bladder.

On the third day after the operation the patient's temperature rose to 104°. This was soon brought down to 100° by the administration of two or three five-grain doses of antifebrin. The stitches were removed on the tenth day, and the drainage-tube on the fifteenth day after the operation; but the discharge continued for two months, when the wound finally closed, and the patient has gained flesh and is entirely free from pain.

Case 5. Mrs. A. N. T. suffered with cramping pains in the epigastric region, and after taking a cathartic passed three small stones by the rectum. Operation May 23, 1889, assisted by Dr. E. Porter, of Columbus, Ohio. The contents of the gall-bladder consisted of 160 small calculi, which were removed and the patient made an uninterrupted recovery.

Case 6. Mrs. J. M. R., 27 years old, had been suffering for two years with pain in the stomach and region of the liver. This pain had gradually increased until it became almost unbearable, and hence she sought relief from an operation. The temperature of the patient was 100½° for several days previous to the operation, which was performed July 4, 1889, assisted by Drs. H. D. Arnold and A. F. Piper. The stones in this case were 370 in number, quite small in size, and all crowded in the gall-bladder. After removing this, I explored the ducts very carefully from the outside, and discovered in them three good-sized calculi, which I had to crush with forceps before I could dislodge them. The sac being considerably larger than the external opening, I carefully cut away a small portion of it before stitching it to the abdominal walls, as in the other cases. The temperature did not rise above 100°, and the patient made a rapid recovery.

AGUE CURED WITH NITRATE OF POTASH.

BY J. B. JOHNSON, M. D.,
WASHINGTON, D. C.

Two weeks ago I was called to see Mr. K., a delicate man, forty-four years old, who had been suffering for the last week with the quotidian form of intermittent fever. He informed me that his chill was

so severe, and had shaken him so violently that it caused the window-sash to rattle as if in a storm. His tongue was coated, and his bowels were constipated. I commenced my treatment of his case by giving him a mercurial purge of five grains of calomel, with ten grains of blue mass, to be taken at once, and to be followed in three hours by a dose of three grains of sulphate of quinine; the latter to be continued in three-grain doses, every three hours, until thirty grains had been taken. I saw him again, the second day after my first visit, and to my disappointment found the quinine had not stopped his chills. I then decided to try the effect of nitrate of potash in his case, and prescribed the following:

℞ Potasii nitratis . . . . . ℥iij
Aquæ destillatæ . . . . . f℥iv
Syrupi simplicis . . . . . f℥ij

M. Sig. Shake well and take a tablespoonful every three hours.

In two days I called to see the man and was gratified to find that the mixture had stopped his ague on the second day. Finding him somewhat anemic, I prescribed the following:

℞ Cupri arsenit (tablet triturate) . . gr. $\frac{1}{100}$
Aquæ destillatæ . . . . . f℥ij

M. Sig. Shake well. Dose, a tablespoonful every three hours.

The eighth day after my first visit I found him entirely free from the ague, and directed him to have his bottle of arsenite of copper refilled and to continue its use for several days.

Reports of Clinics.

N. Y. POST-GRADUATE MEDICAL SCHOOL.

CLINIC FOR DISEASES OF CHILDREN—PROF. JOHN H. RIPLEY.

Sub-acute Rheumatism.

Dr. Ripley first presented the following case: A little girl, five years old, who began to be ill five days before, complaining of pains in the neck and headache. The next day her neck was stiff, and she said her hands and feet hurt her. That night she was restless and did not sleep well. Yesterday she grew very lame, so that she did not care to walk across the floor. She lost appetite and towards evening had fever, and her joints grew stiffer. Her mother said that in last Septemper the child had an attack similar to this, which was confined to one arm and lasted only two days. The three other children had had no such symptoms, nor was there any family history of rheumatism. The child does not live in a damp place, nor on the ground floor, and there has been no exposure. Examination showed both shoulders tender to pressure; also tenderness along the sides of the neck. The right wrist was somewhat swollen and tender. The child's chest was rachitic. The heart showed no abnormalities. The knees were not swollen, and the child said they were not painful; but the mother volunteered the information that they do pain her, because the little girl stoops peculiarly. An article was thrown upon the floor and the child was told to pick it up. She was seen to reach for it in that stiff, awkward manner which creates a suspicion of spine disease. This symptom warrants investigation.

Inspection showed that the spine was straight, excepting a very slight lateral curvature. There was no angular projection of any of the vertebræ.

Dr. Ripley asked how the presence or absence of Pott's disease might be positively determined. Such symptoms, he said, as pain on pressure, pain on movement, on the suspension of the child by the head, the deformity, etc., were not altogether diagnostic. But there was one method worth all the rest. The patient is laid on his belly, the feet are seized with one hand, and making counter-pressure with the other hand against the spinal column above the seat of the curvature the body is carefully bowed backward, thereby obliterating the curvature if the case be not one of spondylitis, or causing pain and proving the impossibility of straightening the spine if the case be true Pott's disease. Of course in many instances the diagnosis of this condition is comparatively easy, but there occur cases in which it is a difficult matter to say whether the patient has or has not disease of the spine; and it is in these doubtful cases that he has come to learn the value of the preceding test. Many years ago he was visiting the wards of a certain N. Y. hospital, in company with a prominent physician of this city, where was shown a case that had been diagnosticated as Pott's disease, and had been exhibited as such during the several months' sojourn of the little patient in the hospital.

It occurred to the doctor to apply the test above mentioned, when, to the surprise of every one, the spine was completely straightened. The incident taught a lesson to those present, and Dr. Ripley trusted that its recital would help to impress this test and its importance upon the minds of the students.

In the patient before the class the manner of stooping would also direct attention to hip-disease. The child still lying upon the face, it was noted that there was no difference in the length of the limbs; that the lines of the gluteal folds were about even; and that striking against the soles of the feet did not cause pain. In doubtful cases, where these signs are not plainly manifest, it is known that seizing the leg and bringing it into abduction will cause pain because this motion crowds the head of the femur into the acetabulum. This is a test that Dr. Ripley has always found very reliable. The present patient complains of no pain from this manœuver. The case, then, is one of sub-acute rheumatism, in large part muscular.

Dr. Ripley ordered the following treatment, expecting the child to be well in a few days:

℞ Acidi cresotinici . . . . . ℥i
Sodii bicarbonatis . . . . . ʒii
Aquæ menthæ pipentæ . . . . . f℥iiss
M. Sig. A teaspoonful every three hours.

Congenital Syphilis.

The next patient was a colored boy, twenty-one months old, who, when undressed, showed great emaciation, flattening of the chest and large abdomen. His respiration was chiefly abdominal. The child kept up a continuous crying, and every time he was touched would shrink away and cry louder as if in pain. The mother brought him to the clinic believing he had spine disease, for she had noticed a "lump" on his spine. As the child was laid upon his face a marked prominence was noticed over the lower dorsal and lumbar vertebræ; not sufficiently angular to be characteristic of Pott's disease. But this might be due to the fact that many vertebræ were involved. Seizing the feet and bowing the spine backwards did not produce any pain, and furthermore it entirely obliterated the curvature; making it clear, as well, that no adventitious tissue caused the deformity, but that it lay in the misdirection of the spinal column. Dr. Ripley said that it might be at once concluded that the child had not Pott's disease but that the apparent curvature was due to rachitis. Further evidence of this disease was found in the shape of the chest and of the head, and in the muscular weakness and emaciation, as also in the retarded dentition (for the mother said that the child did not get his first tooth until after he was one year old). The only cause of delayed dentition is rachitis. This child had been fed on breast milk, which, as far as could be learned, had been plenty and of good quality. The child had also of late been taking other foods which he had eaten with good appetite and had apparently digested. It was possible, therefore, to exclude unsuitable feeding as the cause of the rachitis, and attention would naturally be directed to the next most prominent cause of this disease, namely, syphilis.

The evidences of syphilis in a child of this age would be, first and foremost, glandular enlargements. There might also be a history of snuffles, skin eruption, mucous patches, notched teeth, etc. In this patient both epitrochlear glands were found to be as large as peas; the post-cervical and inguinal glands were also enlarged, and on the body and thighs were the stains of an old eruption. These signs are sufficiently characteristic to make a positive diagnosis of congenital syphilis.

The treatment recommended was: Hydrarg. chloridi mitis grain $\frac{1}{20}$, three times a day, at first; and later cod-liver oil; with perhaps a change in the administration of the mercury to inunction if there was no improvement under its administration by the mouth. Fresh air was a very necessary hygienic resource in these cases.

Foreign Correspondence.

LETTER FROM INDIA.

Medical Practice in Bombay.—Private Dispensaries.—Charges for Consultations.—Consultations.—Crowding in the Profession.

Having finished his studies, a medical graduate of Bombay University opens a dispensary. The very idea of a medical man opening, keeping, and conducting a dispensary is repulsive to every sentiment of medical dignity and ethics. This is the ever-stand-

ing reproach to the medical profession in Bombay. How, and by whose ill-advice the medical graduates first began to keep dispensaries with them, is hard to conceive; but that it is a medical degradation is not at all to be denied. Nowhere in America we find a practitioner conducting his own dispensary. Now, as for the condition of such dispensaries: they are kept in the veranda of the house. They are ill-lighted, and as a consequence, they are gloomy and repulsive. Generally directly behind them are the privies. Every now and then they are kept in mere dark snugs, so small that two men cannot freely pass abreast. As a rule these dispensaries are very dirty and disorderly. The practitioners have no idea of neat and orderly arrangements of bottles and other appliances of a dispensary. Stranger to the idea that he should not keep a dispensary, he is yet a greater stranger to that of arranging his dispensary in a neat and elegant style. One would see in these dispensaries some two or three cupboards with lot of dirt and dust, and some dirty, filthy medical bottles in them, scattered here and there without any aim or end in view. There are one or two school-benches for patients to sit on, but without any back for them to lean on. On one side there is an ordinary side-board, where the compounder of the practitioner fills up the bottle according to the prescription written in the dispensary by the practitioner. These compounders are ignorant of English, or the only English that they know is to read the names of medicines in the prescription, and on the bottle labels. The table on which they dispense medicine is soiled by spattering of water, droppings of medicines, and making up of ointments.

The dispensaries are utter strangers to neatness and cleanliness. Everywhere disorder and filth reign supreme. Towards evening, these dispensaries are the seats of gossiping for loungers in the shape of friends or patients of the practitioners. In the morning when there are some patients gathered together, the practitioners prescribe, and charge nothing for the advice to, or examination of patients; but they are satisfied with the collection of twelve cents for three ounces of mixture to patients. Their visiting fee is seventy cents; they are never bold enough to undertake any surgical operation, or risky obstetric duty. Such cases they refer to hospitals, if the patient is poor, or call out the military professors of the college to conduct the case if the patient is rich enough to pay; thus losing excellent opportunities of becoming experts in some select specialities, and so remaining mere prescribers all their life long. Even in their consultation, they would never call out their senior medical brethren but the military surgeons of the hospitals; so jealous are they of one another. During their leisure hours, they would never think of writing articles either in the vernacular or English on medical, surgical, or on any other branch in which they feel themselves strong and sure. They never aspire to acquire name and fame in this way. They have no stock of well-selected medical authors, that may be called their library. They do not seriously study out one or the other of so many branches from the fertile field of medicine.

There are in Bombay no medical associations, or those that exist are not much to speak about. The profession is entirely over-crowded. On Chundunwady main road you may see medical signs at an average of perhaps every ten houses. On account of such a large number of practitioners, and but a limited intelligent public to patronize them, the competition was at first very keen; then it got over keen, and now it is degrading, when instances are fast multiplying of practitioners paying three and four visits charging a fee for the first one only. This is specially the case with beginners, as they want to set up in direct competition with those already established, and to draw away as many patients from others as they can.

Many young practitioners of Bombay are full of conceit and vanity. They think they know everything, and that others do not know anything. They belittle their senior medical brethren and would not take them in consultation; but they would think too much of their late military professors, howsoever young and inexperienced these latter may be. No doubt some of the practitioners are in a very well-off position; but they are the oldest of the graduates, both of the College and of the University, and they are very few and far between. The bulk of them are yet in a precarious state; some, perchance may yet rise to eminence, the others may remain behind just where they are now.

The status of the profession is not so gloriously high in Bombay as it is in Europe and America. To elevate its status is to elevate that of its members, and the only means consists in their adopting a proper code of medical ethics and acting up to its very

letter and spirit by each and every practitioner of Bombay.

Periscope.

Classification and Treatment of Tumors of the Bladder.

In his recent address before the International Medical Congress, at Berlin, Sir Henry Thompson gave the following classification and description of tumors of the bladder.

1. The mucous polypus—which is not to be confounded with prostatic outgrowths of similar form, these being inadmissible in any scheme comprising vesical tumors—resembles polypi of the nasal cavity, but is more compact and solid in structure. Hitherto, this product has been found in young children only.

2. Papilloma. The papillomatous growths appear in two forms, the essential character being that the structure of the characteristic portion always resembles that of the natural papillæ occurring in certain parts of the digestive canal. The constituent element consists of a prominent fold of simple membrane, supported by connective tissue containing a large arterial twig as a central axis, while the outer surface of the membrane is closely covered by a layer of cylindrical epithelium, or, much less commonly, by the ovate or spherical variety. Formerly these growths were called "villous," to which it was usual to add the term "cancer," although the implied allegation was entirely unwarranted by evidence. When these prolongations are very long, slender, and floating in the bladder, the papillomatous growth is termed "fimbriated." When a considerable portion of fibrous tissue is present, rendering the growth more solid, the designation "fibro-papilloma" is more appropriate. These growths form very slowly at first, but when developed give rise to repeated attacks of hemorrhage, which in time become continuous and copious, thus terminating life. They are the most commonly met with of all vesical growths, and their symptoms have been often mistaken for those of renal disease. Microscopic examination of the urine will sooner or later (especially if the bladder is washed out with water and the débris scrutinized) detect specimens of the growth, which are quite characteristic, and absolutely decisive that the growth is present. Moreover, on careful inquiry, it may be ascertained that the bleeding is found occasionally, sometimes frequently, to appear in a manner which can rarely or never be met with in renal hemorrhages. The patient commences an act of micturition with clear or almost bloodless urine, and at the end of the act bright florid blood is mixed with the stream, or appears alone at the close. This fact determined, the bleeding is without doubt vesical, and if for a considerable period of time there is still but little pain experienced, and the act of micturition is as a rule not very frequent, the bleeding is certainly not due to a sarcomatous or carcinomatous growth, and is therefore very probably significant of papilloma.

Sir Henry said that he knew no styptics which appeared to control the hemorrhage from this source, although he had seen all the known remedies abundantly tried. Treatment by local injections is apt to provoke rather than check the flow of blood.

3. The simple myomatous tumors are not very uncommon; they are not accompanied by any characteristic signs of their presence, but have sometimes papillomatous growth on their surface. Nothing further remains to be said here in relation to diagnosis, except that their progress is slow and the characters of malignant growth are absent.

4. Tumors made up of fibrous tissue chiefly, more or less associated with small nuclei interspersed. Sometimes these are in large quantity, a fact which leads to a graver estimate of their character, as indicating that they probably possess a tendency to return after removal. Both these and the preceding kind involve the deep structures of the bladder, and cannot be entirely separated by any operative procedure; while, on the other hand, many examples of papilloma, especially when growing from a pedicle, may be completely removed, and often do not return.

5. Epithelioma, the nature and character of which in the bladder are those of this growth in all other parts of the body.

6. Scirrhus, or "cancer" properly so called, not occurring until after the middle term of life has been reached, is occasionally met with in the bladder.

7. The round and spindle-celled sarcomata, formerly known as "encephaloid," are sometimes met with in children, but affect not infrequently the adult also.

There are three cases of these sarcomata in the series.

The diagnosis of malignant disease of the bladder is not difficult. Examination of the rectum furnishes valuable information. Scirrhous growth is very hard, irregular in form, and is thus unlike ordinary senile prostatic enlargement, that is, the so-called "hypertrophy" occurring in elderly men. The sarcomata are full and rounded in form, more elastic to the touch than "senile enlargement," and far more rapid in their rate of increase in size. Epithelioma, slow and restricted in growth, may exist several years before presenting a tumor sufficiently dense to be recognized by palpation or by sounding. In malignant disease pain is a more or less constant symptom, and some hemorrhage is liable to appear, increasing at a later date; it is thus distinguished from papilloma, which is rarely recognizable by the rectum, or even by the sound, manifests its presence first by hemorrhage, often at an early date, and is rarely painful until quite the later stage of its history. In all the three forms of recurring or malignant growths, microscopic observation may corroborate a diagnosis based on the signs and symptoms mentioned, but cannot by itself establish one.

In regard to treatment Sir Henry said: In all cases in which we can ascertain the presence of malignant disease—carcinoma, sarcoma, epithelioma—I am strongly of opinion that it is useless to attempt to remove the growth, and that such interference is liable to aggravate the sufferings of the patient rather than otherwise, and perhaps hasten his end.

Setting these cases aside, I am not less strongly of opinion that it must almost invariably be our duty to recommend an operation for removal, not only when the disease is obviously not malignant, but when there is any reasonable doubt on the subject, which will in the course of the operation be cleared up, and the procedure can then be limited or not, according to the judgment of the surgeon.

In relation to cases in which doubt may arise it must not be forgotten that papillomatous growth may be present as a secondary growth upon another form of tumor in the bladder, so that its presence among the débris examined does not demonstrate the presence of a simple uncomplicated papilloma. No doubt in a large majority of cases the simple growth alone is present, but the exceptional condition is not very rare. It is on this account that I often practice and advise a small perineal incision to be made in the median line, opening the urethra in the membranous portion, so that the surgeon may introduce his index finger into the neck of the bladder. This proceeding I have recommended and much practiced during the last ten years in obscure cases, under the title of "Digital Exploration of the Bladder." When the patient is under the influence of an anæsthetic firm suprapubic pressure enables the operator in all ordinary cases to determine with his finger the size and nature of the tumor. If it be a simple pedunculated growth, as papilloma often is, the introduction of an appropriate forceps will mostly suffice at once to remove it. If, on the contrary, it is found to be large, occupying a wide base, or is otherwise evidently unfitted for treatment by the simple proceeding referred to, the suprapubic operation can be at once performed in the usual way. This I have frequently done, and have never found that the preliminary incision described interferes in any way with the subsequent operation, which is conducted precisely as if no such "exploration" had taken place. When a large prostatic or other tumor is encountered in the rectum it is possible that the finger may not reach the bladder, and so may be incapable of exploring the cavity, but in these circumstances the "digital examination" is wholly unnecessary, the condition in question demonstrating that the case is not one of simple removable tumor, but is probably an example of malignant growth. But it may be said that the diagnosis of a vesical tumor may be readily established by means of the Leiter endoscope. I long ago tested its value, having employed not only the earlier but the latest and most improved form of that instrument. Let me say first that the employment of it in the cavity of the bladder involves much irritation in some cases, far more than that which follows the use of the sound. Secondly, that in presence of a tumor which the slightest mechanical contact causes to bleed, the observation is mostly an imperfect one. Thirdly, that the instrument is rarely necessary to determine the fact of the tumor's presence, that being ascertainable in nine cases out of ten by the ordinary methods already alluded to. Lastly, it is assumed to furnish the means of ensuring a view of the growth which shall enable the operator to determine whether it

is peduncular and easily removable, or the reverse. In regard to this important matter, I admit that the object may be attained, but in the majority of cases I am certain it cannot be thus decided, as when the tumor is not seen in profile and when the bleeding occasioned permits only an imperfect view, a far more accurate idea can be obtained by "digital exploration," which never produces the severe cystitis, becoming chronic and confirmed, which unhappily too often follows prolonged manipulation with a rigid cystoscope in the diseased bladder of an elderly patient. I have performed "digital exploration" upwards of a hundred times and have never met with any serious, far less fatal, issue to that simple operation.

Finally, supposing that by any process whatever the presence of a manifestly carcinomatuos or sarcomatous growth has been discovered I can say nothing, as already indicated, in favor of operative measures for its removal. It is always possible to extirpate the growth, which largely involves the walls of the organ itself, and rapidly reappears after the attempt has been made, although large masses may have been taken away and an apparently almost empty cavity has been left as the result of the procedure.

The palliative treatment for all patients thus affected consists in the avoidance of habits, occupations, and any amount of exercise found by the experience of each individual case to produce serious increase of hemorrhage; the maintenance of the digestive power and healthy activity of the functions which support life is as far as possible to be ensured; and lastly, the adoption of all means, especially towards the closing stage of a case which is certainly destined to be fatal, in order to alleviate suffering which is usually severe and prolonged unless dealt with unflinchingly, as it ought to be in such painful circumstances. The ample use of morphine, usually most effective by subcutaneous injection, should be adopted, so that although unable in any way to check the progress of the malady we may at least mitigate the most terrible accompaniment of its distressing and inevitable course.

Substitute for Milk for Infants.

In the *Buffalo Medical and Surgical Journal*, September, 1890, Dr. Delancey Rochester describes an attempt made, early in March, 1890, to wean a girl baby six months old, because its mother's milk was insufficient. The baby objected to the bottle, and could not be induced to take food by spoon. The foods tried were sterilized milk (Meigs's mixture), malted milk and Carnrick's food. So determined was the objection on the part of the baby to artificial feeding, that she cried and fretted so much at each feeding time as to cause a considerable rise of temperature and vomiting of everything except breast milk. Her temperature ran as high as 104° F. in the groin. The stools were not very frequent nor very bad in character. After all attempts at artificial feeding had proved worse than useless, a wet-nurse was procured and the baby again flourished. After the fever had subsided and the vomiting had ceased, the baby broke out in an eruption that was as similar to the measles eruption as could be imagined. The eruption did not irritate her, and it disappeared in a few days.

About June 1 the wet-nurse's milk began to give out, and partial artificial feeding was begun, Meigs's milk and cream mixture, sterilized, being the food employed. On this the baby did well. The wet-nurse's milk having given out entirely by the end of a week, the sterilized milk was used alone. For two weeks the baby gained in every way—weight, firmness of flesh, quiet sleep and happy waking hours. Then the stools began to show curds; but as in every other respect the baby was doing well, nothing was done for this. The last day of June and first of July were excessively hot days, and the baby wilted completely—feverish, restless, fretting and finally vomiting. Stools remaining as they had been for about a week previous, of good color, but containing curds. By the advice of Dr. Hopkins she was given sodium bromide to quiet her restlessness, and cool baths to reduce her fever. Nevertheless, she vomited every time that milk was given to her. Finally, she was given toast water and white of egg for twelve hours, with no vomiting. At the end of that time a little malted milk was tried, but she retained it not more than five minutes, when she vomited profusely.

Dr. Rochester then began to think what he could give temporarily as a food, until the hyperemia of the stomach should subside and the baby could again take milk in some form. White of egg and toast water given cold he knew she could take, so he thought he would look up the exact composition of egg, and see whether by some addition he could not make a food that would

supply all the necessaries for life and growth. In Routh's *Infant Feeding* and Landois' *Physiology* he found analyses of egg—white and yolk—that substantially agreed. The percentage composition of yolk of egg as given by Landois is:

Water	51.5
Proteids	15.0
Fats, etc.	30.0
Mineral matter	1.4
Pigment extraction	2.1

A glance at this will show that the albuminoids and fats bear about the same relation to each other that they do in human milk. The problem then before us is to dilute the yolk of egg sufficiently with water to make the actual proportions the same as in milk. To do this, of course it was necessary to obtain the weight of a yolk of egg. Dr. Rochester weighed several, and found that each weighed about one ounce—some a little less. Calculating, then, on the total weight of the yolk as one ounce, and remembering that it contained 51.5 per cent. water, to reduce the fifteen parts albuminoids to two parts, it was necessary to add seven ounces of water to the one yolk of egg. The amount of sugar in yolk of egg is very slight, being included in the "etc." added to fats in the above analysis. So, to bring the sugar up to the required amount, it was necessary to add sugar of milk. As there is normally seven per cent. sugar in human milk, this would mean in eight ounces a little over half an ounce. This would make a mixture by weight consisting of:

Yolk of egg	1 oz.
Water	7 oz.
Sugar of milk	½ oz.

For the convenience of the household, Dr. Rochester always makes these proportions by volume, so he measured the half-ounce of sugar of milk and found that it filled six teaspoons in an ordinary medicine glass, so the following formula was prepared:

℞ Take yolk of egg . . . . . one
Sugar of milk . . . . . 6 teaspoonfuls
Filtered water . . . . . 7 ounces

Dissolve the sugar of milk in the water and add gradually to the yolk of egg, stirring constantly.

This was fed perfectly cold, in small quantities at a time, for twelve hours, gradually increasing the amount and lengthening the intervals, until finally the full amount was given four times in the twenty-four hours. He once tried warming it slightly—not enough to coagulate the albumin—but the baby objected to it warm, so that was not tried again.

The baby retained this food from the first. After he began with it, it was no longer necessary to give the sodium bromide; but the baths were kept up, three or four being given daily. She was dressed very lightly and made as cool as possible. Luckily the weather also changed and we had three or four cool days. For sixty hours she lived on the egg food alone. During this time the fever left her entirely, and she again broke out in a copious rash, as much like measles as the previous one. At the end of the sixty hours, as she began to show dislike for the egg food, Dr. Rochester tried again the malted milk. The baby now retained it and seemed very fond of it. So it was gradually substituted for the egg food.

The advantages of this egg food are that it contains all the necessary ingredients for life and growth in the proportions in which they exist in human milk, although in somewhat different form; that it must be given cold, and that it is slightly laxative. It is an advantage that it must be given cold. This has a beneficial action in overcoming the hyperemia of the stomach, and prevents further inflammatory developments. It is an advantage that it is slightly laxative, for it thus aids in the discharge of any milk curds that might be in the bowel ready to set up irritative action. This is really a great advantage, for in the congested state of the stomach this baby was unable to retain any laxative medicine, even calomel in small doses being rejected.

Suprapubic Lithotomy.

At a meeting of the New York Surgical Society, April 23, 1890, Dr. A. J. McCosh presented a patient from whose bladder he had removed nine calculi weighing in all four hundred and sixty grains. The wound in the bladder had been about an inch in length and through this the stones had been removed. This opening had then been sewed up, except a slit left for a drainage-tube. A perineal opening was then made, and after some difficulty, on account of an enlarged prostate, a tube was introduced into the bladder for perineal drainage. Some trouble had been caused by occlusion of this latter tube by mucus during the first

few days, and during this time the urine had come entirely through the suprapubic opening. A large perineal tube was introduced and perfect drainage thereby established. Thirteen days after the operation the suprapubic wound had closed. The perineal wound was now almost healed, and most of the urine now came through the penis. The speaker had reported the case to emphasize his appreciation of the advantages of the perineal opening. It had been very noticeable that whenever the drainage through the perineal opening was insufficient and the urine was forced to find outlet through the suprapubic incision, the patient's general condition had changed for the worse. His temperature went up a degree or more, his pulse increased in frequency, and his appetite failed. When the perineal drainage was re-established, the man became himself again. The speaker was much impressed with the result, and in operating upon other old patients, this one being seventy-two years of age, he should certainly make the perineal opening, while in younger ones he would also favor this opening and the suturing of the bladder wound as recently advocated before the society by Dr. McBurney.—*New York Medical Journal*, August 30, 1890.

Conception with Unruptured Hymen.

Dr. W. Macfie Campbell, of Liverpool, read before the Edinburgh Obstetrical Society, April 9, 1890, a paper published in the *Edinburgh Medical and Surgical Journal*, September, 1890, in which he describes the case of a young lady who was brought to him by a relative of the young man to whom she was engaged, as she had not felt well lately. Something about her appearance caught Dr. Campbell's attention as she entered the room, and he made inquiry as to her menstruation as soon as possible. She had not been unwell for three months, but that had occurred before. She was listless, tired, breathless, and did not know what she felt. She said she was always plump, and did not think her bust or figure increased. Examination of the mammæ revealed dark areolæ, distended cutaneous veins, and a milky fluid was easily expressed from her nipples. By the stethoscope the fetal heart was readily detected. Dr. Campbell thought it prudent to ask the relative to step into another room, and then told his patient that she was pregnant. He had frequently had to make such an announcement, but had never seen it received with such amazement and incredulity. "Utterly impossible," the patient said, but still with something in the expression which meant that there was a possibility. Still insisting, she told Dr. Campbell that opportunity having twice offered, her fiancé had got into her bed, and had had imperfect intercourse with her. No penetration nor attempt at penetration had been made. This was afterwards corroborated by the young man. On examination, the blue appearance of the vulvar mucous membrane was well marked, and the hymen was perfect, but admitted the forefinger without causing much pain. The young man was so positive, that Dr. Campbell saw he feared some other paternity. He was however assured that the young woman was *virgo intacta*. The parties were married soon after, and it was not until six weeks after that that penetration was effected, with a sensation of rupture.

Some years ago Dr. Campbell had two confinement cases within a few days, in which both husbands told him they could not understand their wives' pregnancy, as intercourse had never been perfect. In one case he had to divide the distended hymen bilaterally to allow the head to emerge; in the other there was no great difficulty in dilatation. Dr. Gooch relates a case of a lady privately married, in whom he diagnosticated pregnancy, and was met by the statement of impossibility. Her husband had avoided injury to the hymen, and both considered pregnancy impossible. The event, however, proved Dr. Gooch to be right. Dr. Braun, of Vienna, gives three instances of the same. In the first case coition had taken place in a dilated urethra, and Dr. Braun supposed ejaculation had taken place prematurely. Delivery took place without injury to the vagina, the hymen rupturing at the last moment. In the second case, a girl of sixteen years confessed to one imperfect attempt at intercourse. The orifice in the hymen only admitted a goose quill. The third case was exactly similar in age and history. Dr. Braun draws the conclusions that an unruptured hymen is no proof of virginity; that an individual may exist as a virgin in the anatomical, though not in the gynecological sense; and that pregnancy is possible without penetration. Surgeon-General Francis relates the case of an officer's wife, in whom pregnancy was de-

clared impossible by husband and wife, the reason being a tense hymen, which had resisted penetration, and which only gave way after a long delay in delivery.

These cases are of great interest, as throwing doubt upon the theories of uterine activity in the act of impregnation, and of exact apposition of the orifices of the urethra and cervix as being necessary; and rather point to the entrance of the semen into the uterus, and further, as being due to inherent forces, or ciliary action of the vaginal mucous membrane.

Experiments with Orexin.

Since the publication in the REPORTER, August 16, 1890, of a brief note upon orexin, there has appeared, in the *Münchener Med. Wochenschrift*, August 19, 1890, an article by A. Beckh, describing a series of experiments with muriate of orexin. The experiments were conducted in the medical ward of the city hospital of Nuremberg, and were begun soon after those of Penzoldt. Orexin was administered to twenty-two patients who suffered with loss of appetite from various causes. A good effect was produced in seventeen cases; in one case the result was doubtful, because it was difficult to decide whether the patient's loss of appetite had been simulated or not; and in four cases the remedy failed completely. It was given to patients with anemia, chlorosis, and tuberculosis, and to some with anorexia produced by different acute and chronic diseases. In two cases of chronic disease of the stomach it was given with very good results.

At first orexin was administered in gelatin-coated pills, and later in capsules—which is the preferable way. Beckh began with doses of four or five grains a day, which were increased, as required, by the third day to seven and a half grains. A larger dose than this was not given, and a large glass of meat broth or milk, or a plate of soup, was always taken by the patient in addition. In a few cases disagreeable effects, such as burning in the stomach, and vomiting, were noticed.

Beckh concludes that orexin is worthy of further experimentation as a stomachic, and that it is to be recommended in anemia and tuberculosis. It may also be employed with caution in chronic diseases of the stomach, but not when there exists anatomical change in the mucous membrane; as the drug is a strong irritant. For the latter reason also it must be given with a certain quantity of fluid, preferably meat broth or soup.

Death from Nitrous Oxide.

A death from nitrous oxide is reported from Montreal. A man, aged twenty-four, went to the office of a dentist to have a tooth extracted, and requested to have the gas administered. After assuring himself that the patient was not suffering from heart or lung disease, the dentist administered the gas. No sooner had the tooth been extracted than the patient gave a gasp and fell over in the chair. He was placed upon the floor and artificial respiration performed, but without restoring animation. The patient was not under the influence of liquor, and five hours had elapsed since last taking food (breakfast). The purity of the nitrous oxide was tested shortly after the accident by the president of the dental association, Dr. Beers, who himself inhaled it from the same inhaler. The verdict of the jury was that the man died from syncope, caused by the administration of the gas, and they exonerated the dentist from blame.—*Druggists' Circular*, September, 1890.

Women Physicians in India.

From a parliamentary paper which has just been issued, we gather that a considerable number of native women have taken up the study of medicine in India. At the close of the session 1888–9 there were twenty-four female students at the Calcutta Medical College, fourteen at the Campbell Medical School, and five at the Cuttack Medical School. At Agra, during the year, seven young women received licenses to practice. At Lahore there were nineteen, and at Madras thirty-nine female medical students, one of the latter being the first to take the degree of M. B. at the Madras University. There were also female students at the Grant Medical College of Bombay, and at the Government Medical Schools at Poonah, Ahmedabad and Hyderabad. The movement initiated, or at all events patronized, by Lady Dufferin is thus giving good fruit, and as the objections entertained by many over here to the practice of medicine by females do not apply in India, with its peculiar social conditions, this result must be a matter for congratulation.—*Medical Press*, September 3, 1890.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

PHYSIOLOGICAL ACTION AND USES OF COCAINE.

The physiological action of cocaine will be understood most easily by contrast with that of curare. The latter is well known as the type of peripheral motor-nerve paralyzers; cocaine, on the contrary, exerts its action upon the peripheral sensory nerves. They resemble each other, according to Dastre, involving only the terminations of the nerves; the nerve trunks preserve their excitability, and may even have it exaggerated. Again, while curare paralyzes the vaso-constrictor nerves within the blood-vessels, cocaine, on the contrary, excites them.

Cocaine in small doses appears to act as a general stimulant, producing a feeling of exhilaration, with an increased flow of speech, wakefulness, and a more rapid development of ideas, without, however, increased capacity for brain work. In this respect cocaine resembles morphine by contrast with caffeine. The heart and respiration are accelerated. In larger doses it causes slight dimness of vision, a feeling of tension and constriction of the forehead, with perhaps slight headache, dizziness, and great restlessness. The latter symptom is due to hyper-excitability of the muscles, and is explained by the condition of the nerve-trunks. In still larger doses, the effect of cocaine in constricting the blood-vessels is evidenced by coldness of the extremities. The rise in blood-pressure which occurs is due in part to this and in part to acceleration of the heart's action.

Respiration is accelerated by cocaine, while under poisonous doses it becomes embarrassed and shallow, and stops before the heart. The pupil is dilated through stimulation of the sympathetic system. General analgesia develops only late and under poisonous doses; so that it is of no clinical importance.

Toxic doses of cocaine produce in some cases death preceded by collapse, cyanosis and convulsions, the respiration especially being affected. In some cases the patient becomes very restless and loquacious, the speech is thick, and the sentences unfinished, the mouth and throat dry, the patient is giddy, and staggers on attempting to walk, and is covered with a cold, clammy sweat. In some cases collapse and unconsciousness have developed speedily, and have been succeeded by active delirium. Autopsies in fatal cases have demonstrated the presence of cerebral and visceral congestions, especially of the kidney.

Prolonged use of cocaine has resulted in chronic poisoning, and in the production of the "cocaine habit." The former is said to be characterized by great excitement, hallucinations chiefly of sight and hearing, and great weakness of the lower limbs, almost amounting to paresis.

Cocaine is used in medicine and surgery

principally as a local anæsthetic. The limits of its applicability have not yet been determined. It is most serviceable, however, when applied to the more delicate mucous membranes, such as those of the eye, nose, urethra and vagina, where the peripheral sensory nerves are close to the surface and from which absorption is rapid.

Space will not permit a detailed mention of all the cases in which cocaine can be used; in general it may be said to be wherever the irritated nerves can be reached, whether exposed in a hollow tooth or bared by cancerous ulceration, as in the breast. Hypodermically it has been used, with more or less success, in the extraction of teeth, the opening of buboes, the excision of small tumors, to prevent the pain caused by iodine when thrown into the tunica vaginalis for the cure of hydrocele, and in various other minor surgical operations. It forms a useful addition to soothing ointments, such as those for acute eczema or for pruritus.

Its property of contracting blood-vessels and drying mucous membranes makes it especially serviceable in acute coryza. It is most effective in the congestive (first) stage, but even when there is a profuse watery or mucous discharge, it gives more relief than any other remedy. A watery solution should be used, and eight or ten drops of a four or five per cent. solution may be snuffed up each nostril as often as the necessities of the case demand.

Internally, cocaine has been employed to check vomiting, and in some cases with great success. Gastralgia has also been relieved by it.

In what has just been said, an effort has been made to point out the most important physiological actions of cocaine, and to suggest the classes of cases in which it is likely to prove useful, rather than to enumerate the separate affections in which it may be used. Whenever it is used, it should not be forgotten that cocaine is as much a poison as morphine or strychnine, and that, being more uncertain in its effects, it should be watched with more care. It would seem to be most dangerous to nervous patients with weak hearts.

ATROPIA FOR NOCTURNAL INCONTINENCE.

To get at the truth is better than to have false hopes; and it is with great satisfaction that we call attention to a paper by Dr. R. Bruce James in the *Archives of Pediatrics*, September, 1890, which seems to definitely decide a very important question in therapeutics. As the readers of the REPORTER know, Dr. Simon Baruch, in December, 1888, read a paper before the New York Academy of Medicine in which he discussed nocturnal enuresis in children and its treatment, bringing to the notice of the medical profession the great value of the alkaloid atropine in this affection, as evidenced by results obtained in quite a number of cases in which he had used it. But he added that since his cases had not been very long under observation he could not predict the ultimate result to be obtained.

Dr. William Perry Watson, of Jersey City, read before the American Medical Association, at its last meeting, a paper in which he reported in detail thirty unselected cases of enuresis, all cured or greatly benefited by this drug. Prompted or encouraged by such glowing accounts of the virtue of this drug, many of the profession resorted to its use with great confidence and expectation. But a long and faithful trial of it has scored another failure in our search for specifics. For some have found that the number of cases of enuresis cured by atropia, during its administration, is great, but the number remaining cured when the drugged is stopped is small indeed. Dr. James, while resident physician in an Orphan Asylum in New York, had under his charge many cases of enuresis that had resisted belladonna, strychnine and the other lauded remedies. After hearing Dr. Baruch's paper, he determined to give atropia a trial. Fifteen of the worst cases, among the smaller

children, from three and one-half to nine years old, in which no cause for the trouble could be made out, were selected. Some of them wet themselves alternate nights only, others every night, while a few suffered from diurnal as well as nocturnal enuresis.

The plan of treatment was to make a solution of atrophia sulphate, of which one teaspoonful represented one-hundredth grain of the drug. Of this solution, for the first night, each child had one teaspoonful at 6 and another at 9 P. M., and this being increased by one teaspoonful every night until a controlling dose was reached for each case. None of them were benefited by less than four-hundredths of a grain at night—*i. e.*, two-hundredths of a grain at 6 and two-hundredths of a grain at 9 P. M.—while others required as much as eight-hundredths of a grain, divided as above; one child was given as much as one-tenth of a grain at night without showing symptoms of poisoning.

Nothing short of the quantity that produced full physiological effects was of any avail. This point was insisted upon by Dr. Baruch in the paper referred to. After the controlling dose was ascertained for each case, it was repeated every night for about one month, when the drug was withheld altogether. It was found that many of the cases were completely relieved, while others were not benefited. The latter were immediately put on their controlling dose and an attempt made to diminish it, but without much success in this, though in no case was it found necessary to increase the original controlling dose, except in one case. Of the cases completely relieved, the enuresis returned in all, with one exception, in periods ranging from one to six weeks. The child that was cured was a healthy boy, but slightly affected. These children were put on their controlling doses as they relapsed, and an attempt was made to taper off with them also; and in some cases a considerable reduction of dose was effected. The cases were kept under close observation for eight months, during which time many of them would go without the drug, or on reduced doses, from one to four weeks without wetting themselves. But sooner or later the relapse would occur, and at the end of the eight months they were but little better than when we started treatment.

It can be seen how any one, who has not kept a long watch over his patients, could readily arrive at the conclusion that permanent relief had been obtained in most of these cases, especially if he depended on the matron or person in charge of his cases for his information; for after such complete relief afforded by the treatment she is slow to acknowledge a relapse, and it is only after the closest scrutiny and questioning that you can arrive at the actual state of affairs. Such, at least, has been Dr. James's experience; for not a few of the cases he reports here were marked cured in his notes, after questioning the matron carefully; but, visiting the wards himself early in the morning, he found that such was not the case. No doubt this element in human nature is largely responsible for erroneous conclusions arrived at and published by those who rely too implicitly on the information gained from attendants.

In only one case did any symptom of poisoning occur, and in this not sufficient to warrant a suspension of the remedy or even a diminution of the dose. Under the long-continued use of the drug, though in such large doses, there was observed no bad effects from it, but, on the contrary, the children, being relieved from the stigma of being bed-wetters, were brighter and less constrained than when the drug was left off, with the consequent return of the enuresis. Some of the children, though under the age of five years, were so ashamed of their affliction that, on finding they had wet their beds at night, they would exchange their wet sheets for dry ones from the cots of their slumbering neighbors, thus shifting the coming lecture to innocent shoulders: so great was the effect of the so-called moral treatment.

Every case was absolutely controlled so long as the treatment was kept up, except one case, in which it lost its effects after some months of complete relief, and this from some unknown cause which was never overcome, though the drug was pushed to a dangerous point. It is a matter of no little regret that, after such a promising beginning, the final result shows such a little gain. On October 1, after eight months of treatment, of the fifteen cases, two cases were cured, and these mild cases. Two others were benefited, in that they did not wet their beds so often. One it ceased to benefit, while ten showed little or no improvement when the drug was stopped.

In conclusion, Dr. James says that since the long-continued use of atropia has no ill effect, no tolerance is established that requires an increased dose, and since undoubtedly the vast majority of these cases can be controlled by the drug, atropia is for these children and for their mothers a valuable friend. When a child is too large to wear diapers, or they cease to be effectual, we can with confidence offer a substitute in the shape of a full dose of atropia, to be repeated every night till the child has outgrown his infirmity; and this point can be tested by having the drug withheld from time to time. Dr. James put many other cases of enuresis on atropia, and it controlled the trouble in every child under twelve years of age. Thirteen months after the treatment was begun, these children were about as they were six months before, still receiving nightly doses of atropia, and improved only as might be expected with their advance in years. As to those over twelve years old who received this treatment—which were quite a number—they did badly. Dr. James cannot recall a case that was benefited in the least.

We may regret that careful observation should dispel the illusions created by somewhat premature conclusions, but it is of the greatest importance that we should not be deceived as to the value of any method of treatment. The one discussed above has great value if rightly understood, but it is evidently not the panacea which some have thought it.

THEINE IN THE TREATMENT OF NEURALGIA.

Every now and then cases of neuralgia are reported which have been treated successfully by the hypodermic injection of theine. The local anæsthetic action of this alkaloid was, we believe, first brought to the attention of the profession by Dr. Thomas J. Mays, about four years ago, who, from his experimental and clinical investigation, concluded that its physiological action is not identical with that of caffeine, and that its analgesic action is more prompt and more permanent in neuralgia than that of morphine or of any of the other agents in common use for the purpose of deadening pain.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

ANNUAL OF THE UNIVERSAL MEDICAL SCIENCES. Edited by Charles E. Sajous, M. D., and seventy associated Editors. Illustrated with Chromo-lithographs, Engravings and Maps. Five volumes, octavo. Philadelphia: F. A. Davis, 1890.

The early promise of this admirable publication has been so well fulfilled that the *Annual* is worthy of comparison with the best works of a like character in France and Germany. How much this implies will be understood by those who are familiar with the latter. When the *Annual* was first projected it seemed hardly possible that it could so soon reach its present position. But the enterprise of the publisher and the tact and skill of the editor have brought it about. As it stands to-day, the *Annual* is a work of very great value and one which every intelligent physician might well have and consult.

MEDICAL DIAGNOSIS, WITH SPECIAL REFERENCE TO PRACTICAL MEDICINE. A Guide to the Knowledge and Discrimination of Diseases. By J. M. Da Costa, M. D., LL. D., Professor of Practice of Medicine and of Clinical Medicine at the Jefferson Medical College, Philadelphia, etc. Illustrated with engravings on wood. Seventh Edition, revised. 8vo, pp. 995. Philadelphia: J. B. Lippincott Company, 1890. Price, $6.00.

Da Costa's *Medical Diagnosis* occupies a unique place in medical literature. From the time the first edition was published, in 1864, to the present time it

has been the most widely known and most highly esteemed work on the subject. It is one of the first to be taken up by the intelligent student and one of the last to be laid down, and then, perhaps, only when he ceases to handle books of any kind. So great is the esteem in which it is held by some, that it almost amounts to affectionate reverence. The explanation of this high regard is to be found in its manifold excellences. It is the most comprehensive treatise on diagnosis extant, yet its delineations of disease are never tedious and prolix. Other books there are which give as truthful accounts of the symptoms of disease and their significance, and in individual cases, perhaps, with greater precision and in more detail; but no author in this department of medicine has so far succeeded in preserving throughout his work such a nice balance between the essential characteristics of disease and the unessential details, and so giving to the reader a complete but concise description. Moreover, the style of the author is pictorial and captivating; each disease as described seems to stand out from the general background of diseases with clear-cut, distinct features; the picture is vivid but not exaggerated in its coloring.

The classification adopted by the author is almost purely clinical, the diseases being grouped according to their marked symptoms. This classification possesses decided advantages, especially for students, who learn first the course and symptoms of disease, and later their pathology. It has this drawback, however, that the student is apt to conceive of disease as a group of symptoms instead of a pathological process, and as affecting one organ alone instead of only manifesting itself in a particular case more prominently in one organ than in another.

Taken as a whole, this is the best book of its kind on the subject. One cannot help, as an American, being gratified to learn from the preface to the present edition, that a second edition of the German translation, by Dr. Engel and Dr. Posner, has appeared in Berlin; that a Russian translation has been issued; and that a French translation, by Dr. Laurent, is now in progress.

FIFTH ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF THE STATE OF MAINE. For the fiscal year ending December 31, 1889. 8vo, pp. x, 304. Augusta: Burleigh & Flynt, 1890.

The annual publication of reports by State Boards of Health indicates in a general way the increased interest that is being taken in hygiene and the prevention of disease. Many of these reports are crude efforts and clearly show that the information they have been able to collect is neither full enough nor precise enough to be of much value. Nevertheless the existence of such Boards and the occasional issuing of statements bearing upon the public health, must eventually make an impression for good and arouse the people to the importance of cleanliness and disease prevention, if only from an economic point of view.

The present Report contains very little of peculiar interest, because the health of Maine during 1889 was fairly good. The report of the Secretary, Dr. A. G. Young, of Augusta, shows that much good work has been done in the way of vaccination, school-house inspection, water analyses, etc. Much valuable sanitary information is given in a series of fifty or more abstracts, entitled, "Various Sanitary Topics," selected by the Secretary. F. C. Robinson, a member of the Board and Professor of Chemistry in Bowdoin College, contributes a paper on "Arsenic in Wall-paper." He examined "several hundred" samples of wall-paper, from different parts of the State, and he states that "upwards of one hundred of them are free from the poison or contain the merest trace. In fact, but three only have been found which are unmistakably dangerous."

As the Report has been prepared for all classes of persons, a glo-sary of technical terms has been added for the benefit of those unacquainted with their meaning. This is thoughtful. Altogether the Report makes a very satisfactory showing.

GEOLOGICAL SURVEY OF NEW JERSEY. Annual Report of the State Geologist for the year 1889. 8vo, pp. 112. Camden, N. J.: F. F. Patterson, 1889.

That admirable man and excellent geologist, Dr. George H. Cook, who was appointed State Geologist March 30, 1864, died September 22, 1889, and the present Report contains a brief notice of his services. The work done during 1889 was planned by him, and he also outlined a scheme for its continuance. Dr. Cook's former assistants, Mr. Irving S. Upson and Mr. Frank L. Nason, continue to act, the former being in charge of the office; while Prof. John C. Smock becomes consulting geologist.

The Report contains, first, notes on the Geodetic Survey, by Prof. E. A. Bowser. Mr. Frank L. Nason reviews the geological studies of the Archæan rocks from 1836 to the present time. Sufficient data, he says, have been collected to show that the rocks of the Archæan are not homogeneous, but that they are belts which are similar and persistent. A systematic attempt has been made to discover some orderly succession of rocks, or groups of rocks, which will hold true for the whole Archæan field. The result has been the selection of four types, named for the locality in which the rock prominently occurs. These types are: Mount Hope, Oxford, Franklin, and Montville. The first is in part the feldspathic gneiss of Prof. Smock, and in part, the hornblende gneiss of Dr. Britton. The second is in part, probably, the syneite gneiss of Prof. Smock, and the hornblende gneiss of Britton. The third is probably a biotite gneiss. The fourth is the white or crystalline limestone, although this has not been proved to be of Archæan age. The paper concludes with a statement of the economic relations of the Archæan Highlands.

A less elaborate article, by the same author, follows. It is a study of the Triassic or red-sandstone and Trap rocks. Mr. George W. Howell has a short paper on drainage, with reference to the Pequest and Passaic rivers; and C. C. Vermeule one on Water Supply and Artesian Wells. Mr. Lewis Woolman writes upon the Artesian Wells of Atlantic City. The volume concludes with some statistics of iron and zinc ores.

The geological survey of New Jersey has fallen into excellent hands. Certainly the present Report will add considerably to the scientific reputation of Prof. Cook's successors.

—A cement for slides holding preparations in glycerin is prepared by Dr. S. Apathy (*Zeitsch. Wiss. Mikr.*) by melting together equal parts of Canada balsam and paraffin (60° melting point), and continuing the heat over a moderate flame until terebinthinous vapors are no longer perceptible, and the mixture has assumed a golden yellow hue. The mass, hard when cold, is applied by first melting again.

Literary Notes.

—We have received the first number of a journal called the *Review of Insanity and Nervous Disease.* The initial number contains 110 octavo pages. It is to be a quarterly, to contain almost exclusively abstracts, translations and selections, and no number is to have more than one original article. The editor is Dr. James H. McBride, of Milwaukee, Wis., and the agents are B. Westermann & Co., New York, and W. T. Keener, Chicago. The subscription price is $2.00 per annum.

—The *Cosmopolitan* for October is a very handsome and interesting number. Captain Charles King, who recently visited St. Paul and Minneapolis, has in it an illustrated article entitled "Twin Cities of the Northwest" which will prove interesting reading not only to the citizens of these two cities, but also to a great number of readers scattered throughout the country who have watched with astonishment the marvellous growth of these towns.

New Remedies and Appliances.

[In this department, notice will be given of Remedies, Food Articles, and Instruments or Surgical Appliances of which specimens are sent to the Editor; it will bear the same relation to these articles that the department of Book Reviews now does to books.]

Invalid Mattress.

Mrs. H. J. Webb, of Lockport, N. Y., has designed a mattress intended for the use of invalids. The invention consists in an arrangement by which different sections of the mattress may be detached and turned back. The advantages of an apparatus of this kind are well known to medical men, and it is also convenient to know where a thing of this sort can be procured. The sale of the mattress is in the hands of Mr. George H. Webb, of Lockport.

Questions and Answers.

[In this department will be published questions on any medical subject by readers of the Reporter, and answers by the Editor or by other readers.]

Dr. G. W. Ensley, of Waverly, Wash., writes: During the past eighteen months that I have been reading the Medical and Surgical Reporter I have noticed a number of articles pertaining to the mode of administering cocaine, but very little as to its constitutional actions and uses. Will you kindly give a brief account of the latter in an early issue?

[The answer to this request will be found in the editorial columns of this issue of the Reporter.]

Notes and Comments.

Southern Surgical and Gynecological Association.

The Southern Surgical and Gynecological Association will be held in Atlanta, Georgia, November 11, 12, 13, 1890.

The papers announced to be read are: The President's Annual Address, George J. Engelmann, M. D., St. Louis, Mo.; How Shall We Treat Our Cases of Pelvic Inflammation? R. B. Maury, M. D., Memphis, Tenn.; The General and Local Treatment of Gangrenous Diseases and Wounds, Bedford Brown, M. D., Alexandria, Va.; Further Study of the Direct and Reflex Effects of Lacerations of the Female Perineum, J. H. Blanks, M. D., Nashville, Tenn.; Abdominal and Pelvic Surgery in America, Joseph Price, M. D., Philadelphia, Pa.; Intra-Ligamentous Ovarian Cystoma, Cornelius Kollock, M. D., Cheraw, S. C.; Anatomy and Pathology of the Ileo-Cæcal Region, Richard Douglas, M. D., Nashville, Tenn.; Wet Antiseptic Dressings in Hand Injuries, Wm. Perrin Nicolson, Atlanta, Ga.; The Best Route to the Bladder in the Male for Disease or for Foreign Bodies, Hunter McGuire, M. D., Richmond, Va.; Suprapubic Cystotomy in a Case of Enlarged Prostate, Wm. H. H. Cobb, M. D., Goldsboro, N. C.; Indications for Cholecystotomy, A. M. Owen, M. D., Evansville, Ind.; Uterine Moles and Their Treatment, J. T. Wilson, M. D., Sherman, Texas; Strictures of the Male Urethra, W. F. Westmoreland, M. D., Atlanta, Ga.; Treatment of Urethral Strictures by Electricity, W. Frank Glenn, M. D., Nashville, Tenn.; The Surgical Treatment of Empyema, J. A. Goggans, M. D., Alexander City, Ala.; Cases in Abdominal Surgery, I. S. Stone, M. D., Lincoln, Va.; Rectal Medication in Pelvic Troubles, W. Hampton Caldwell, Lexington, Ky.; Conservative Surgery in Injuries of the Foot, J. T. Wilson, M. D., Sherman, Texas; The Management of the Infantile Prepuce, George Ben. Johnston, Richmond, Va.; The Ultimate Results of Trachelorrhaphy, Virgil O. Hardon, Atlanta, Ga.; Further Observations on the Dangers of Operative Delay in Prostatic Troubles, with Personal Experience, R. D. Webb, M. D., Birmingham, Ala.; Clinical History of the Epicystic Surgical Fistula, with Cases, John D. S. Davis, M. D., Birmingham, Ala.; Foreign Bodies in the Air Passages, with Report of Cases, John E. Pendleton, M. D., Hartford, Ky.; Cholecystotomy, W.

E. B. Davis, M. D., Birmingham, Ala.; Two Cases of Laparotomy for Intestinal Obstruction, J. T. Jelks, M. D., Hot Springs, Ark.; Is Gonorrhœa Ever a Cause for Pelvic Inflammations? J. R. Buist, M. D., Nashville, Tenn.; and papers the titles of which have not been sent in, by W. O. Roberts, M. D., Louisville, Ky.; L. S. McMurtry, M. D., Louisville, Ky.; Wm. D. Haggard, M. D., Nashville, Tenn.; Hunter P. Cooper, M. D., Atlanta, Ga. Information in regard to the meeting may be obtained of the Secretary, W. E. B. Davis, M. D., Birmingham, Ala., or the President, George J. Englemann, M. D., St. Louis, Mo.

Hydrophobia Notes.

[The following is a summary of such information as the REPORTER has been able to gather from newspaper publications in regard to the Pasteur Institute in New York. Fuller and more exact reports, direct from Dr. Gibier, would be welcomed by the profession.]

Since the point to which the report in the MEDICAL AND SURGICAL REPORTER, July 5, carried the notes on hydrophobia, Dr. Gibier has expressed his opinion in regard to the case of a French Canadian who died in Bellevue Hospital, June 10, with his arms tied to the side of the bed, and four men holding him, while the physicians dosed him with morphia and gave him chloroform. Gibier says it was a genuine case of hydrophobia. The following cases were received for treatment at the Pasteur Institute in New York:

June 12, a woman bitten by a cat was taken to the Pasteur Institute in New York, where Gibier had "strong hopes" of saving her life.

June 12, a woman of New York, bitten by a cat.

June 14, a young man bitten by a dog in Rhode Island; a woman bitten by a dog at Jamaica (N. Y.?)

June 17, a boy, twelve years old, bitten two weeks before by a dog which was at once drowned. Dr. Gibier refused to treat him, saying he would certainly die of hydrophobia. [He got well, however.] The same day a woman in Brooklyn, bitten by a friend's Newfoundland dog.

June 28, a man from Brunswick, Me., a colored boy from Asheville, N. C., a colored girl from Augusta, Ga., a man from Norwich, Conn.

July 2, a man over seventy years old bitten, October 6, 1889, by a dog, came to Gibier, who told him he could do nothing for him, and that he was a "doomed man." [He got over his symptoms, however, and did not die as Gibier predicted.]

The same day a young working girl came from Massachusetts, bitten by a dog thirty-three days before—dog immediately killed and nothing known as to its having rabies.

Also came a small boy, of New York, bitten, June 30, by a dog, which was shot by a policeman. A man of New York, wounded by a cat, was sent away to watch the cat closely and return if it developed signs of rabies.

July 6, a daughter of a physician of New York, bitten on the hand "some time ago."

July 7, two men from Brooklyn, bitten July 4, by a bull dog. The dog was placed under surveillance of a veterinarian. (One account says it was "crazed" by fireworks and was killed at once.) The same day also a veterinarian of Massachusetts, bitten May 5, in the leg, by a dog he was watching for rabies.

July 10, Mr. Joel Palmer and two children, of Voluntown, Conn., bitten July 9, on the hands by their own shepherd dog, which was chased and killed.

July 11, an infant two years old, in N. Y. bitten in leg by a dog that "escaped."

July 13, a man from Arizona, bitten in the ear and hand by a skunk two months before.

Also a commercial traveler of New York, bitten in the leg in Connecticut; and a boy from New Hampshire, bitten on the elbow.

July 18, a boy bitten in the leg, and another boy bitten in the arm.

[Gibier sailed for Europe July 19.]

July 21, a physician, his wife, and a servant who were not bitten, but had received upon the hands saliva from a dog afterwards suspected of having rabies; also a man from New Brunswick bitten four weeks before.

July 27, a woman of Hamburg, Conn., Mrs. Rosenthal, said to have showed symptoms of hydrophobia a few days after being bitten by a rabid dog, was reported to have been successfully treated by Gibier.

August 4, a young woman from Somerville, Mass., badly lacerated in the thigh and arm by a "mad dog" was received at the New York Pasteur Institute. On the same day a small boy from New Jersey, bitten on the thigh by a dog that afterwards died with symptoms of rabies; and a man from Springfield, Mo., bitten on the hand.

The dog "had to be shot before his jaws could be loosened" from the man's hand.

August 13, Moses Moore, of Arizona, bitten on the foot by a skunk a few days before, was "on his way to the Pasteur Institute in New York."

[August 31, Gibier returned to New York.]

September 10, a boy fourteen years old from Nebraska, bitten 28 days before by a dog, which had bitten a cow, which died ten days later of "hydrophobia." The same day a young man from Norfolk, Va., bitten by a "mad dog," August 29; also Miss Maggie Quenzer, of Plainfield, N. J., bitten in the hand on that very day by a dog which was killed, and which Gibier said was rabid because he found its stomach "terribly diseased" and "containing stones, nails, and pieces of wood." [A child bitten by the same dog at the same time was *not* taken to Gibier, and we believe has fared as well as his patient.]

Florida's University.

The plans of the buildings for the projected university at Tarpon Springs, Fla., of which Dr. Charles E. Sajous, of Philadelphia, is President, are now in hand, and it is stated lectures are to be commenced on October of next year. At first there will be only one building, but others are to be added. The lines of Harvard are to be closely followed, and there will be faculties of medicine, law, theology, arts, veterinary surgery and dentistry.

The university has been mainly founded for students of debilitated health who are compelled by the severity of the Northern winters to forego study during those months and to travel in the South. The medical department will give special attention to the study of climatic treatment of pulmonary affections. There will be a sanatarium and colony founded in connection with the university, and the whole will form a health resort for the winter months corresponding to the European Riviera.

Bacteriology Run to Extremes.

The *Medical Record*, August 30, 1890, says editorially: Is it not about time to halt a while in our restless search after the microscopical accompaniments of certain diseases, and pause to consider what we are accomplishing, and whether there is not some danger of becoming men of one idea, narrow to the extreme in our conception of what disease actually is, and of how we ought to combat its ravages. It may be that we are no different from other men, yet it would seem as though medical men might be justly called the Athenians among men of science, in that they "employ themselves in nothing else, but either in telling or in hearing some new thing," and when they have found that new thing they let everything else go and cling to that alone. It is thus with the study of bacteriology. It has been ascertained almost to a certainty that the tubercular process, for example, is associated with a certain form of microscopic growth which is not found as an accompaniment of other diseases. It is therefore assumed, correctly no doubt, that this micro-parasite is the cause, either directly or indirectly, of tuberculosis. Other microbes have been found in relation with other diseases, and it has also been assumed that a causal nexus exists. This is well enough, it is a plausible theory, and one that offers great hope of advance in the therapy of certain diseases, and if it does not blind us to the actual necessities of treatment and lead us to neglect the plain indications while running after some specific microbicide, there is no objection to its further study and amplification. But here is where the tendency of mankind, in general, and seemingly of the medical profession, in particular, to ride a hobby to death betrays itself. Some are not satisfied in accepting what has already been proven, but they must assume what remains to be, and which possibly never will be proved. They look for the bacillus in every departure of the human organism from health, and they run a serious risk of making themselves, as well as the science which they study, ridiculous. Not long ago it was gravely announced in an Italian journal that some one had discovered the bacillus of old age. Of course that was intended as a joke, but so ready at the present day are some minds to see the infinitesimal in pathology that not all could see the joke, and several medical papers reproduced the item containing the announcement of the great discovery in all seriousness, never for a moment seeming to see in it anything but the most natural discovery, and one that would explain many of the lesions found in those of advancing years. But there are other things put forward in good faith which are almost as ridiculous. Not long since a Russian

investigator examined the water obtained from melted hail-stones, and found it to contain several varieties of bacteria. There was nothing very remarkable in this discovery, for it would have been strange had no bacteria been found, but what was remarkable was the conclusion which the man drew. He thought it very probable, since rain, snow, and hail had all been found to contain micro-organisms, that there was a specific, and hitherto undescribed, disease to which only those were liable who had been exposed to a storm and had been wet to the skin by water containing these peculiar bacilli. It is not the search after microbes that is absurd, but the conclusions which many run to without first establishing their premises. We are not yet in position to assert that there can be no disease without its specific micro-organism, and those who do so maintain are in danger of making their science a subject of ridicule to men whose range of vision extends beyond the microscope field. They also interfere with therapeutic progress by turning men's minds away from the phenomena of diseased action and hunting after an invisible foe, which may after all be found to have less power for evil than it is now credited with.

Maggots in the Stomach.

In the *Deutsche Medicinische Wochenschrift*, June 26, 1890, Dr. Landon, of Elbing, reports the case of a child, six and a half years old, who was attacked with vomiting and diarrhœa after vaccination. The stools contained a large number of worms. The mother stated positively that the discharge of worms did not occur every day, and that these were only present in the stools and not in the vomit. The child died in eight weeks, with manifestations of extreme exhaustion. It was robust and healthy at birth and had been fed with artificial food: flour and milk prepared the day before using. Through carelessness and lack of cleanliness, it is possible the disease resulted from the presence of the ova of flies in the food, a condition referred to by Kirchenmeister in his text-book. The parasites were examined by Virchow and Chun. The latter called the larva that of the horse-fly—*tabanus*—which lays its eggs in the nasal cavity of the horse. Displaced larvæ find their way through the pharynx into the stomach and fasten themselves to the mucous membrane by means of a pair of hooks, situated on the head, so that the stomach of a horse may be literally studded with the parasites. A similar state of affairs might be present in the human stomach.

Autopsies in such cases are rare on account of the generally favorable course of the disease, and none was made in Landon's case; so that it is not as complete or as conclusive as might be wished.

New Methods of Treating Erysipelas.

The *Bulletin Médical*, May 28, 1890, contains a brief review of some of the more recent methods of treating erysipelas, which is sufficiently interesting to warrant reproduction.

Rosenbach's method consists in first washing with soap, not only the erysipelatous area but also all the surrounding surface of the skin, and the bathing of the same parts every day with a five per cent. solution of carbolic acid in absolute alcohol. Brilliant results are reported, not only as regards the progress of the disease but also in controlling the febrile phenomena. Absolute alcohol alone is said to have produced favorable results.

Nolte paints twice a day all the diseased surface, and for an inch around it, with a mucilage of gum arabic mixed with three or five per cent. of carbolic acid. Good results are reported. Ebstein mixes the carbolic acid with vaseline.

Koch applies with a soft brush a thin layer of the following ointment:

℞ Creolin . . . . . gr. xv
Iodoform . . . . . ʒi
Lanolin . . . . . gr. cl

The parts are then covered with a sheet of gutta-percha. It is said to give good results especially in erysipelas of the face and of the hairy parts.

Nussbaum and Brunn employ ichthyol, with or without collodion. The results are said to be both favorable and prompt.

Hallopeau saturates several thicknesses of muslin with a solution of one part in twenty of salicylate of soda, and applies the muslin to the affected parts as a mask. Over this is placed rubber plaster to prevent evaporation. Relief is said to be almost immediate, and recovery to occur from the third to the fifth day.

Hueter's method strikes me as heroic. He employs injections of diluted carbolic acid into the healthy skin, in amounts of ten to fifteen grams, divided into several injections. These are made at a distance of one-third or half an inch from the edge of the diseased part. The following solution, freshly prepared, is the one used:

℞ Acidi carbol. puri
Alcoholis absoluti . . . . . āā ♏ xlv
Aq. destill. . . . . f℥ iii

This method is very painful, and is applicable only to grave cases of erysipelas of the face and hairy parts.

Kraske scarifies the edges of the erysipelatous patch before applying to it the antiseptic substance. Lauenstein's advice is to limit incision exclusively to the healthy skin, and then to cover the parts up with dressings moist with a solution of carbolic acid or corrosive sublimate.

The method of Wolfler consists of mechanical compression by means of strips of adhesive plaster applied upon the healthy skin at the margins of the diseased parts, so as to circumscribe the latter completely. Kroell proposes the use of rubber tubes or bands in place of adhesive plaster.

Execution by Electricity.

Dr. C. F. MacDonald, President of the State Commission in Lunacy, on October 8, made a report to Governor Hill, of New York, on the execution of Wm. Kemmler. He asserts that death was sudden and painless, and that despite all hostile criticism the first execution by electricity was a successful experiment and will be regarded in the future as a step in the direction of a higher civilization, being infinitely preferable to hanging.

He recommends that there be but one electrical plant, located in the centre of the State, with a competent electrician in charge; that there be especially constructed apparatus of at least 3,000-volt power, which will do no injustice to any electrical lighting company, as would be the case with commercial dynamos; that the voltage employed should not be less than 1,500 nor more than 2,000; that a careful record be kept of every point, and that an official report to the Governor be made within 10 days after the execution.

NEWS.

—Dr. Walter D. Green has removed from 214 South Fifteenth street, to 131 South Fifteenth street, Philadelphia.

—A committee has been appointed by the Philadelphia County Medical Society to draft a law that will restrict the practice of hypnotism to its legitimate channels.

—Dr. James Farrar Stone has just completed a new building for the physical training school and gymnasium for women and children at 1808 Green street, Philadelphia.

—Dr. William A. Edwards, formerly of Philadelphia, and now of San Diego, California, was married, October 6, to Frances Louise, daughter of Mr. and Mrs. Alfonso Taft.

—It is reported that Dr. Roberts Bartholow will shortly resign the Chair of Therapeutics at the Jefferson Medical College, and this is said to be on account of incapacity caused by overwork.

—Pestonjle Hormusjle Cama, the philanthropist who founded the Cama Hospital at Bombay, has given 25,000 rupees to the Bombay University, in order to encourage medical education among women.

—Dr. Henry McGonegal, who was recently convicted in New York of manslaughter in causing the death of Annie Goodwin by malpractice, was sentenced on October 15 to fourteen years imprisonment.

—The Kensington Hospital for Women, in Philadelphia, has just purchased a large building at No. 136 Diamond street, which will permit the accommodation of twice as many patients as the Hospital can now admit.

—A young woman twenty years old, died in Brooklyn, October 14, from malpractice. It is said that she procured medicine on a prescription furnished by a Brooklyn physician, and that this medicine is to be analyzed.

—A number of New York medical practitioners are said to have organized a Physicians' Musical Club. The Philadelphia *Ledger* commenting on this fact says that "each member should compose some fresh air for the sick-room."

—One of Reed & Carnrick's extensive factories at Goshen, N. Y., was destroyed by fire on September 10. This factory which was devoted wholly to the production of their Soluble Food and Lacto-Preparata will be rebuilt three times the size of the one burned, with machinery correspondingly enlarged.

FOR THE CURE OF

NERVOUS HEADACHES

SEDATIVE EFFERVESCENT

BROMO (WARNER & CO.) SODA

℞ Caffein 1 grain, Brom. Soda 30 grains in each heaping teaspoonful.

Useful in Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Seasickness and Epilepsy.

Dose and Composition.—A heaping teaspoonful, containing Bromo Soda 30 grs., and Caffein 1 gr., in half a glass of water, to be repeated once after an interval of thirty minutes if necessary.

EFFERVESCENT ANODYNE

BROMO (WARNER & CO.) POTASH

℞ Caffein 1 grain, Bromide Potash 20 grains in each heaping teaspoonful.

Useful in Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Seasickness and Epilepsy.

☞ **Physicians** desiring the Potash Salt can obtain the same by ordering or prescribing **Bromo-Potash (Warner & Co.)**, the composition of which is: Brom. Potash 20 grs., Caffein 1 gr.

☞ The composition of the above effervescent salts is such as physicians can use with confidence, and you will please specify **Bromo-Soda** or **Bromo-Potash, Warner & Co.**, when ordering or prescribing to avoid the substitution of other "Bromos." Prepared only by

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

CLINICAL LECTURE.

PURPURA SIMPLEX.—DIAGNOSIS OF GASTRIC DISORDERS.

BY JOHN H. MUSSER, M. D.,

ASSISTANT PROFESSOR OF CLINICAL MEDICINE, UNIVERSITY OF PENNSYLVANIA; VISITING PHYSICIAN TO THE PHILADELPHIA HOSPITAL.

Gentlemen: I will change the regular order of my series of lectures, so that I may present to you a case of some interest, the features of which are ripe for illustration. I will preface my remarks by saying that the different cases I had before you last week are in about the same condition as then. The woman with ascites, who was suffering with severe abdominal pains, has been relieved by the use of codeia, which Dr. Lauder Brunton has found to be a remedy of extreme value in cases of abdominal pain. Opiates constipate, and in the large majority of instances of abdominal disease it is not desirable to produce constipation, and therefore codeia, which does not possess this property along with its analgesic property, may be used. It is given in doses of one-quarter of a grain every three hours. Brunton's method is to begin with small doses, gradually increasing the size, until the patient is relieved of pain. One and a half to two grains may be given every one, two or three hours in the most urgent cases of pain, as in carcinoma, entire relief ensuing. Even the pain of peritonitis may be thus treated, where it is especially desirable to avoid the use of opiates.

Purpura Simplex.

I wish to call your attention now to the appearance of this patient's legs. Yesterday and the day before the eruption with which they are covered was more brilliant than it is to-day. He states that three weeks ago, after a fall (which was merely a coincidence), he noticed some spots on his legs similar to these, but not so extensive. He was admitted to the house three days ago, when, in addition to the rash which was confined to the limbs, he was complaining of pain in his joints, and particularly in the right knee, which was quite tender on pressure. On examining the rash we find that it does not disappear on pressure, and that the surface of the skin is smooth. In other words, the appearance is due to ecchymoses or subcutaneous hemorrhages; and it is a case of purpura. Purpura is a general term for a disease and a symptom, and its presence may be due to quite a number of pathological antecedents. Thus it is a common manifestation of scurvy. It is of most common occurrence in the blood affections, as in the later stages of Hodgkin's disease, and in leucocythemia. It also occurs and has been described in general malignant sarcoma, in septic or ulcerative endocarditis, and in the grave fevers. As a disease, it is known by two or three different terms. Thus we have simple purpura, or purpura simplex; then there is purpura rheumatica, which is accompanied by rheumatoid symptoms; and the graver form, known as purpura hemorrhagica, or "morbus maculosus Werlhofii." In studying the patient before us, we must endeavor to ascertain whether his is a case of symptomatic or of true purpura. From our examination of him, and from the history which he gives, we may at once exclude malignant sarcoma, leucocythemia, the anemias and diseases of the endocardium, the organs usually involved in these affections being free from disease. Scurvy, a very common condition, the cause of which is familiar to us all, is usually found in sailors who have been long at sea upon a limited diet; but at times it is seen in isolated cases on land, or in the form of epidemics in institutions such as this.

Is this a case of scurvy? In the first

[1] Delivered at the Philadelphia Hospital.

place this patient has not been in any institution, and he is not a sailor, nor has his mode of living and particularly his class of food been such as to have produced scurvy. Then scurvy is usually associated with clinical features which are not present in this case. It is a slow disease, while this man's trouble developed suddenly. Then, in scurvy the patient is emaciated, weak, and pallid, presenting a cachectic appearance, with poor circulation, bluish lips, dusky cheeks, small and feeble pulse, and weakness of the heart's action. These usually appear before there are any outward manifestations of the disease. Then follows an inflammation of the gums, their margin becoming the seat of redness and ulceration. They recede from the teeth, and are soft and spongy, bleeding easily. The mouth itself is very sore. This condition of the gums is not present where teeth are missing, and infants when suffering from scurvy never present this affection of the gums. At the same time with this change in the gums subcutaneous hemorrhages occur. At first these are bright, rarely so large as this man shows, and they have the characteristic of developing around the hair follicles, and therefore present a papular feel. This is an anatomical distinction between the purpura of scurvy and simple purpura. This papular sensation may be felt in hemorrhages due to infarcts. The eruption of scurvy does not appear so suddenly, and become uniform so rapidly as does that of simple purpura. In the latter disease the patient will be ill and complaining for two or three days, and then in a few hours the rash will appear, in cases of rheumatic purpura often covering the whole body. On the other hand prolonged failure of health with a gradual onset of the eruption is characteristic of scurvy. In scurvy there is a brawny induration of the muscles, due probably to hemorrhages into their tissues, which is not present in this case. In scurvy there is a quite marked œdema, and the general nutrition of the skin is poor, it being dry and scaly.

This patient shows none of these symptoms as you well see, we may therefore exclude the presence of scurvy. We find on examination some pain, with tenderness in the joints. This is a symptom present in most forms of purpura, and is due to hemorrhage in the synovial membrane. In the rheumatic forms it is often very severe, and is accompanied by stiffness and swelling of the joints.

There are other eruptions, due to the exhibition of drugs which are very similar to that of purpura. Potasium iodide, for instance, in large doses produces an eruption, which is not confined to the limbs, however, but appears all over the body, particularly over the trunk, and which curiously enough often is very painful and tender. A rash also develops in the administration of copaiba. I recall one or two instances where the patients were much alarmed by the sudden development of a purpuric rash after they had been taking copaiba. A scarlatineal rash also often follows the administration of this drug. The drugs mentioned are most liable to be followed by subcutaneous hemorrhages, and as they are often taken secretly for obvious reasons, the fact should be borne in mind. This patient says that the rash intermits, one crop fading away only to be followed by another. This peculiarity is found more particularly in purpura than in scurvy, where the rash is a persistent one. From all of the symptoms I have given to you, I believe that this is a case of simple purpura, notwithstanding the presence of the pain in the joints. This, I believe, would be more severe, were it a case of rheumatic purpura.

Purpura sometimes develops very curiously. For instance, a case occurred in my practice not very long ago, of a middle aged woman who was suffering with severe and repeated hemorrhages from her stomach. There was no evidence of malignant disease of the stomach, nor any symptom of gastric ulcer. The cause of this repeated and persistent hemorrhage was obscure. I washed out the stomach and examined the gastric secretion, but with negative results. The patient soon became exhausted. Hysterical hemorrhages were eliminated. Finally, subcutaneous hemorrhages were noticed, and then general hemorrhages upon the mucous membranes, and death soon followed from a large hemorrhage behind the peritoneum, filling up the space as far as the diaphragm. No organic disease was discovered at the autopsy. The hemorrhage from the stomach took place from a minute ulcer at the gastric end of the œsophagus. The lesson taught by this case is the necessity of suspecting the existence of purpura in cases of hemorrhage arising from no recognizable cause.

Diagnosis of Gastric Disorders.

I wish now to continue our study of some gastric conditions. The patient I had

before you at the last clinic, you remember showed progressive emaciation, while on physical examination we could determine a tumor in the left hypogastrium and presumably attached to the stomach. He presented some dyspeptic symptoms, but there was no pain or tenderness, no vomiting, no hemorrhage. To determine whether or not organic disease exists, certain methods, largely chemical in their nature, are employed. By means of these we are able to determine the ability of the stomach to digest, and the motor power of the stomach, and to discover whether there is the necessary acid present in the gastric juice. You remember I showed you, by means of the administration of salol, that the motor activity of the stomach was lessened. Instead of appearing in the urine in one hour after its administration, which it would have done had the motor power of the stomach been up to the normal, three and a half hours elapsed before its appearance. These tests determine whether there is a functional or an organic disease of the viscus present, and thus far we had ascertained that this organic disease was present, namely, a reduction in the muscular power of the organ.

Next we must examine the gastric juice for the presence of hydrochloric and lactic acids. Hydrochloric acid in large quantity is as much indicative of organic disease as is its absence pathognomonic of carcinoma of the stomach. There are several methods by which the hydrochloric acid is found in the stomach. We must first secure some of the juice. A trial breakfast is given, and in three hours the secretion is taken from the stomach. Formerly the vomited matter was used, but so many disturbing factors were found to be present that a sufficiently accurate reaction could not be obtained. At present the secretion is withdrawn by the stomach-pump, or by means of the syphon alone, when digestion is at its height, normally in three hours after the administration of food. We first determine its reaction, whether acid or alkaline. We then determine which acid is present, hydrochloric or lactic. There are two methods of testing for the presence of lactic acid. The one is very complicated and the other simple, the so-called *Uffelman's test.* In this we use a four per cent. solution of carbolic acid, to which a few drops of neutral ferric chloride is added, producing a steel-blue liquid. A few drops of gastric juice added to this discolorizes the solution, if hydrochloric acid be present. If lactic acid be present, it produces a yellow coloration, and if it is in excess, a reddish yellow. If lactic acid alone is present, a greenish tint will be produced. In examining for hydrochloric acid we may employ the methyl violet and the gentian violet methods. The former gives a greenish blue coloration, if the acid be present.

This man's gastric juice has been examined, and shows a minimum amount of hydrochloric acid. Even yet we cannot decide positively that carcinoma is present, though the association of a diminution in the muscular power, and the diminution in the amount of hydrochloric acid shows that some grave organic trouble of the stomach is present. In grave gastric catarrh there is also a diminution in the amount of this acid, but there would also be more marked symptoms in that condition than are here present. I fear there is grave malignant disease here.

Carcinoma is a local disease affecting either the cardiac or pyloric ends of the stomach, or either curvature. It is not the cancer by itself which causes the symptoms, but they are determined to the localization of the disease, hence the symptoms vary with the position of the growth. It may occur in the lesser curvature without any symptom being observed. Pain is a general symptom of cancer, depending upon whether there is an obstruction or a localized peritonitis. It may be altogether absent if the ulceration be slight. Hemorrhage may also be absent if the growth be not especially vascular. Thus we may have cancer of the stomach existing without any of its cardinal symptoms. Emaciation and cachexia are always present, the cause of the latter, however, not being known. It is thought to be due to an involvement of the liver; but we find it where the liver is not affected. Understanding, then, how carcinoma may exist without its presence even being suspected, or discovered until it is revealed at the autopsy, it is important that the chemical means I have mentioned be resorted to, to aid us in making a diagnosis in obscure cases.

—Oil of sandal wood was first employed by the Chinese, and they as well as the Hindoos give preference to that produced at Mysore. This variety has been found best by European practitioners also.

COMMUNICATIONS.

DENGUE FEVER.[1]

BY ALBERT J. HAHN, M. D.,
NEWARK, N. J.

About five years ago, to effect a change of climate, I went to Texas, and it was but a short time after the re-establishment of my Penates in their proper place, that the member of my family for whose benefit the change had been made was taken ill. General malaise of a few hours' duration was followed by an alternation of chilly shudderings and flashes of heat, a certain amount of stiffness and pain in the muscles of the occipito-spinal region and sacrum, and more severe pains in the joints.

I attributed the ailment partly to a process of acclimatization and partly to the influence of malarial miasmata, gratuitously bestowed upon the new-comer by a little lazily running brook, whose banks were beautifully covered by fig-trees, banana-plants, gigantic reeds, and a great variety of luxuriant exotic plants and weeds; and I treated the case as mainly malarial in its aspect, although my efforts in that direction were not as successful as I had expected.

A few days later I was called to a cottage only a few hundred yards distant on the other side of the brook, by the natives euphoniously called river, because it contained a little water, which is more than can be said of most Texas rivers. I had hardly entered the house and been made acquainted with my patient, when she informed me she had the dengue, and wished me to relieve her at once of those horrible pains in the joints. I was momentarily perplexed. Here was a patient; she had made her own diagnosis, and I did not dare to contradict, in fact I readily and quietly assented. Since the final review for graduation-examinations of my text-book, in which dengue occupied the very tail-end, I had not been reminded of its existence until I was now suddenly and unexpectedly confronted with its reality for the first time—or rather the second, for the first time in my family I had not recognized it.

The term dengue has been applied to an acute febrile condition, accompanied by an eruption, lasting from five to eight days, and occurring in hot climates. The name "dengue" is said to be derived from the Spanish "Dunga," a corruption by the Cubans of the term "Dandy" fever, which latter appellation the affection received from the English negroes at St. Thomas, on account of the peculiar stiff gait of those attacked by the disease. Different writers, however, gave the fever different names, according to their individual real or fancied impression as to cause, prominent symptoms, or locality where it occurred or whence it was imported. Thus we have as the more prominent ones the synonyms of: African fever, Aden fever, Arabian fever, scarlatina rheumatica, break-bone fever, giraffe fever, eruptive epidemic fever of India, etc., etc. Dengue has occurred epidemically and sporadically in India, Persia, Arabia, Egypt, the West Indian Islands, and North and South America; but its history can be traced only to the latter part of the 18th century. The first description of the disease is by Dr. Rush, of Philadelphia, of the epidemic of 1780. Dr. Aitkens records the epidemic at Calcutta in 1824, in which but few persons out of half a million escaped the affection. In 1827 an epidemic broke out in St. Thomas, and after having given a test of its powers to every inhabitant, it visited successively the various islands of the West Indies, and came the following year to the United States, where it raged epidemically throughout the South, and sporadically as far North as New York and Boston, where many cases occurred. This epidemic was most accurately described by Dr. Samuel Henry Dickson, of Charleston, S. C. In 1850 an epidemic visited the Southern States which was well described by Drs. Wragg, of Charleston, S. C., and H. F. Campbell, of Augusta, Ga. Again in 1873 an epidemic visited the Gulf States, at which time in New Orleans fully 40,000 people were affected by the disease within a few weeks. The most recent and widespread epidemic was that of 1880. It covered all the Southern States of North America. At the same time the fever broke out at Cairo, whence it spread all over Egypt.

To trace, however, definitely the source of the latter epidemic in this country has proved a failure. To prove the origin of dengue fever has also been unsuccessful. All agree that dengue greatly depends upon climate, seasons and atmospheric conditions; all agree that dengue is an infectious fever; but whether it is also contagious in character the historians upon the various epidemics

[1] Read before the Practitioners' Club.

leave, by virtue of their totally diversified opinions, an entirely unsettled question.

Dengue, as a rule, makes its appearance abruptly, although a general malaise of a very short duration may initiate the fever. The person may enjoy the very best of health, when suddenly severe frontal headache, aching of the eyeballs, nausea, chilliness, with occasional flashes of heat, and pains in the limbs, set in. There is rarely a distinct chill, but more often chilly shudderings passing down the muscles of the spine. The cephalalgia is intense, and soon the muscles of the occipito-spinal region become stiff, and the pains in the joints, resembling those of articular rheumatism, reach their highest point of intensity with the height of the pyrexia. The temperature ranges from 101° to 106°, and proportionate is the general suffering of the patient. The pulse, bounding and full, runs from 90 to 140 per minute. The very height is usually reached at the end of the first twenty-four hours; after which time the disturbance of the temperature and pulse, and the other symptoms, gradually decline, manifesting, however, in the evening of each day a slight aggravation over the conditions of the morning. In addition to the above symptoms, hemorrhagic tendencies are manifest, such as epistaxis, and bleeding from the gums and rectum, and, in severe cases, hematuria and hemoptysis. Glandular enlargements are very common. The glands most commonly affected are the lymphatic glands in the groin, axilla and neck; and these enlargements are apt to continue for weeks and even months after disappearance of the dengue. Anorexia is the rule, and often there is general gastric disturbances, gastralgia, vomiting and diarrhœa, and jaundice; in the latter half of the disease when the pyrexia has commenced to decline, an eruption makes its appearance on various parts of the body. It may resemble erythema, lichen, rubeola, urticaria, etc., but more commonly it resembles the rash of scarlatina. Desquamation follows in some cases after the lapse of a few days. Insomnia may be an annoying and persistent symptom.

An attack of dengue lasts from five to eight days, and, while in some cases the patient may feel just as well immediately after the attack, in most cases the effects will be felt for weeks thereafter. The pains in dengue are of such a severe nature, that the disease has been termed the sum total of human misery; but cases of an exceedingly mild character in all its symptoms are not wanting. Relapses occur occasionally after the second or third week; but these are usually of a mild type and brief in duration.

As dengue is an entirely non-fatal disease, its pathology is wholly unknown, and its prognosis is always favorable, except in the very feeble ones at the extremes of ages, the exceedingly young or very old; for dengue excepts no age or sex. When death does occur, it is always due to some fatal complication, such as severe hemorrhage, convulsions, abortion or some intercurrent disease.

When we attempt to describe the differential diagnosis of dengue, we are in the first place confronted with yellow fever; for these two have, besides the climate and localities, various features and characteristics in common, so much so in fact that the unicists here—as in the case of diphtheria and membranous croup—have among their advocates, ever since Dr. Osgood, in 1828, promulgated this theory of unity, counted some of the most reputable physicians who had obtained their observations at the bedside of the afflicted. According to Dr. Eugene Foster, of Augusta, Ga., who gathered a vast experience in the epidemic of 1880, the more important points of similarity and dissimilarity are these: dengue has prevailed over Egypt, Asia and India where yellow fever is unknown. Both are arrested by frost. The fever in dengue rises regularly until the acme is reached, remains stationary for a few hours, and then gradually declines. In yellow fever the temperature rises steadily. In dengue the pulse rises in proportion to the temperature, in yellow fever the pulse becomes slower while the temperature rises. The duration of the fever in dengue is from five to eight days, in yellow fever it is seventy-two hours. Vomiting is rare in dengue and frequent in yellow fever. Albuminuria is the rule in yellow fever, the exception in dengue. Hemorrhages in yellow fever are more frequent and copious, especially the hematemesis (black vomit). Dengue is proverbially a non-fatal disease, while yellow fever is very fatal. One attack of dengue is not protective against a second attack nor against yellow fever, and the latter not against dengue, but one attack of yellow fever is usually protective against a second attack.

Dengue and malarial fevers might possibly be confounded, and no doubt in light cases are, for many of the so-called dengue-fever cases occurring at non-epidemic times

are often nothing but malarial fevers. The two fevers have certainly the time of prevalence and geographical distribution in common. The temperature, the eruption and the glandular enlargements in dengue will establish the diagnosis.

From articular rheumatism, dengue is to be distinguished by the fact that in dengue the swelling is peri-articular and attacks also the head, back, etc. In rheumatism we have intra-articular effusions. The heart is never affected in dengue. The glandular enlargement and eruption of dengue will also help to decide the case.

From scarlatina, dengue may be diagnosticated by its articular pains, enlargement of glands and diversified eruption.

A very interesting question presents itself, whether or not our last epidemic visitor, *la grippe*, and the dengue are one and the same. They have a great many symptoms in common; they both are sudden in their attacks; the prostration, cephalalgia and pains in the back and limbs are about the same in both; and the eruption is not uniform in either. The main point of difference between the two lies in the fact that in dengue the symptoms of disorders of the digestive organs prevail, while in *la grippe* the catarrhal symptoms of the air-passages are most prominent. Whether the well-known fact that the diseases of the digestive organs of hot climates correspond to those of the respiratory organs of the colder climates or seasons can be held accountable for this fact, is difficult to decide.

Allow me now to cite two of my cases which occurred to me during my Southern activity.

September 11, 1885, R. F., 48 years old, laborer, who had had dengue in 1866, in New Orleans, and yellow fever in 1876, was suddenly taken with severe frontal headache and pains in the whole body. He had felt slightly chilly previously. His temperature was 103½° and his pulse 120. The next day his pains were severe in all the joints—he had a burning sensation about the sacrum, with nausea, a slightly sore throat, no thirst, a tongue dry, red and glazed. His bowels were normal and his mind was clear. September 13, his skin was very dry, his tongue about the same as the day before. He had vomited once during the night, a very greenish mixture, and felt very sore in the back. He was sleepless and restless, and his face and eyes were flushed. His temperature was 103°, and his pulse was 120. September 14, his temperature was 102°, his pulse 108, and his tongue was slightly moist, but still red. He had a severe attack of epistaxis and several copious watery stools. His pains were much less severe, but he was still very restless. An urticarial eruption was seen on his body and limbs. September 15, his temperature was 100°, his pulse 80, and he felt fairly comfortable and made a ready recovery.

October 8, S. N., a woman thirty-two years old, had felt badly for the last two days—but on this day got pains in her joints and back. Her pulse was 96, her temperature 102°. The next day her pain had increased; she had alternate chills and heat flashes, and was very restless—she had itching over her whole body. Her temperature was 104°, her pulse 120; her tongue was dry with red stripes at the edges. At 6 P. M. she had had several attacks of copious nose-bleeding—she had soreness in the stomach and much pain along the spine. On October 10, her temperature fell one degree. Her menses had appeared the night before—one week ahead of time. She felt very weak and faint. She had patches resembling a scarlatinous rash on her body. Her lips were covered with fever-blisters, and she had a tendency to diarrhœa. On October 11, her temperature was 101°, her pulse 100. She suffered but little, but insomnia was persistent, her eyes and temples and body were slightly jaundiced. She had no more epistaxis, but severe uterine hemorrhage. On October 12, her temperature was 99½°, her pulse 90. She had not yet slept; otherwise she felt much better, although she still had slight aches along the spine. Her uterine flow had decreased much in quantity. On October 13, she was convalescent, the jaundice had disappeared, except from her eyes. By October 14, there was light desquamation of those places where the eruption had occurred.

In concluding this theme I will state that I have seen, and no doubt the gentlemen present likewise, during the spring and summer, here in Newark, a great many cases, which, for want of a better name, I called malarial, but which, had they occurred in a tropical climate would have been termed slight attacks of dengue, and under the proper conditions of heat and soil might have developed into good specimens; while on the other hand the slight attacks of Southern dengue we would up here call simply malarial fever. There is nothing in

a name. The symptoms to which I refer, and which were with very few exceptions not all present in every patient, were in the aggregation the following: General malaise, alternate cold and heat flashes, aching of the eyeballs, pains in the back, stiffness of the occipito-spinal muscles, pain and stiffness more or less severe in the limbs and joints, that could not always be accounted for as rheumatic, even cases with epistaxis, and spitting of blood in tubercular subjects, gastric disturbances, bronchial troubles, sore throat, and an itching eruption in some cases.

Take these symptoms in all, with the ensuing pyrexia, the chilly sensations of a severer and steadier nature, and the accompanying symptoms of correlative aggravation, and I cannot see what is lacking to make it, if not a case of dengue, as close a relative to it as is possible.

THE ORIGIN OF EPIDEMICS.

BY G. W. FUREY, M. D.,

SUNBURY, PA.

Believing that scientific medicine is not limited or circumscribed, and that it may use any facts in its mission to better mankind, I would like to call attention to the relation between disease and certain conditions which are especially the object of study in that branch of science called meteorology. We are all interested in the weather, the climate, and the various conditions belonging to our aërial environment. We notice aërobic micro-organisms dependent upon favorable conditions of the atmosphere for their life, their development and their dissemination. We realize the benefits of a proper adaptation of climate to the wants of our patients and are careful to guard them from the ill effects of sudden changes of weather. We observe epizoötics, such as pink-eye, *la grippe*, catarrhal fever, chicken cholera, horse and cattle distempers following each other around the world. Within ten short years we have seen local rains and floods, cyclones and tornadoes, cease to be classed with exceptional and phenomenal occurrences in our Eastern States; and we have watched the thermometer go up until it registers a mean temperature higher than known to the memory of man, with our winters growing warmer and our summers cooler, our rain belt changed and localized, and the rainfall greatly increased.

It has been proved that the temperature at the earth's surface is dependent upon conditions of the atmosphere, and that the universal tropical climate that produced the Coal Age was not due to the earth's internal heat. If we briefly examine the Coal Age we may be enlightened and assisted in our investigations. Enormous quantities of carbon dioxide mingled with the air of that period. The surface of the earth was more level than at present, giving a greater ocean area, much of which was shallow marsh, in which grew the great flora of the Age. Inhaling and storing up the carbon of the dioxide as woody fibre, it exhaled into the atmosphere vast quantities of oxygen, and thus prepared the air for the existence of man. When the air had at last become respirable and the general contour of the earth correspondingly adapted to the use of man, all but a necessary amount of this carbon dioxide had been withdrawn from the air, and was hidden away beneath the limestone and other rocks of a subsequent period, in the forms of coal, petroleum, and natural gas.

Glass transmits "luminous" heat and is impervious to the passage of obscure, or "dark" heat. It is thus we prepare our garden hothouse or conservatory. Light heat from the sun enters the conservatory, is changed to dark heat, within, and retained by the imperviousness of the glass to that kind of heat. Among the compound gases we find that carbon dioxide, in its relation to the transmission of heat, has the same properties as glass, transmitting luminous heat and reflecting dark heat.

Man has consumed the forests. Each year he mines, in the United States alone, two hundred millions of tons of coal. He has tapped the tanks of petroleum and the founts of gas, and is oxidizing it all—all that vast quantity of carbon—converting it into carbon dioxide. The chimneys, laboratories and furnaces of civilization have been, for a hundred years, oxidizing carbon in the open air. The respiration of animal life has been oxidizing carbon all these ages, and now we find that the product has accumulated over the surface of the earth and is wielding an influence that is assimilating our climatic conditions more and more to those of the age of coal, approximating extremes, so that May weather has been known to temper the rigors of January and

"cool waves" to fan the sweltering summer.

There are a few deep, narrow valleys that have long been known as uninhabitable, because of the accumulation of deadly amounts of carbon dioxide at their bottoms; but more recently, since the increase in the combustion of coal, oil and gas, when every valley has its railroad and every hamlet is a manufacturing centre, perceptible quantities of this carbon dioxide have settled down in all the valleys and are becoming more manifest to us as they exert an influence upon the phenomena of the weather and the climate. Within a year and a half the eastern part of the country has been visited by local floods, the like of which have never been known before, and two of our inland cities have been devastated by cyclones which surpass any that have ever been known in all the land. Of the cyclone which swept through the city of Wilkes-Barre a few weeks ago, the papers said at the time: "This cyclone was born right here in the Wyoming Valley. Tuesday had been a muggy day." "Cyclones are not understood." "The Signal Service knew nothing about the beginning of this storm."

Wyoming Valley is about twenty miles long and about three or four miles wide, surrounded by high mountains, with Wilkes-Barre in its middle. "The weather was muggy" for days, not only in this valley but also generally throughout the East. The air was at rest, so that any accumulation of carbon dioxide that was in the valley, where vast amounts are constantly being produced, had settled down and spread out, forming an envelopment of the whole surface. At ordinary temperatures carbon dioxide is several times heavier than air; but it possesses the property of absorbing ninety times more heat than air possesses; so that its expansion will be relatively greater, and when slightly heated it becomes lighter than air. Now, over this carbon-invested valley the sun had been shining fiercely all the day. Its luminous rays had been transmitted through the layer of carbon dioxide, imparting to it some warmth, causing expansion—rarification. It rose up a little from the ground, and air took its place. Light heat streamed through and was changed beneath to dark heat, and it absorbed more heat, became lighter and rose higher, arching over the valley from side to side, and above the city, held down by its own weight and that of the super-incumbent column of air, and pressed upward by its own lightness and the enormous expansion going on in the natural greenhouse below, where the "muggy" humid air was storing up as dark heat the enormous inpour of light heat of that long summer day.

As the sun was declining in the West, something happened in the vicinity of the city; some inequality occurred in the equilibrium that had lasted since morning, some untoward shaft of heat from below, perhaps, shot upwards, adding to the pressure already there; a small area of the envelope was forced suddenly up, a rift was made, and through it rushed the pent up expansion from below.

This instituted a column of escape with its apex ascending. To fill the threatened vacuum, its apex downwards, rushed a cold column from above. Below the envelope of carbon dioxide, it met with and became part of a heterogeneous atmosphere made up of air, smoke, dust and vapor of water. Meeting thus, under great pressure, heat was lost and taken; contraction and condensation suddenly followed; the tendency to a vacuum was increased, and violent motion was engendered. Conforming with the nebular law, a rotatory movement was assumed by the column of descending vapor; in phalanx the two columns, the hindermost invisible and the foremost enwrapped in a black, funnel-shaped cloud, as a cyclone it struck the edge of the city and mowed its swath of desolution across. Here is a clipping from a paper on the subject: "The large column that moved ahead of the débris seemed three or four hundred feet high and seemed yards in diameter. The roofs, timber, fences and trees were swept along behind like feathers in the wind." The statement by an eye-witness confirms so much of our theory. It was the advance column, the funnel-shaped cloud, that beat down and twisted to pieces the buildings and fences, while the ascending column swept them along like feathers in the wind.

I advance the theory, that the increased amounts of carbon dioxide that have gathered from all sources into our atmosphere produce, as I have described, the change in the weather and climate of recent years and that the alarming frequency with which new species of disease germs have been manifested in strange epidemics lately are consequent upon the same conditions and not merely coincident with them. It has long been known that yellow fever mi-

crobes require a higher mean temperature for their development than do those of other forms of disease.

It is supposed that *la grippe* of last winter sprang into sudden being from a small neighborhood in Russia, for the reason that its specific germs, because of propitious surroundings, shook off the lethargy of their "sleep of ages." Now, if this be probable, who can doubt that there may be lying dormant somewhere, awaiting a similar development, aërobic genera, that lay down to rest long ago, when prehistoric man and the mammoth became extinct.

If space would permit, many facts and suggestions that have come to my mind could be presented to strengthen or corroborate the theory. Here is a sample of what is becoming familiar to the newspaper reader of to-day. A newspaper speaks of a "Strange Disease among Cattle," as follows: "Marshall, Mo., August 27, 1890. John Nicely, a prominent farmer near Arrow Rock, reports a new and strange disease among his cattle, etc., etc."

However right or wrong my theory may be, it is my opinion that "above the clouds" is not the place to view the coming storm. Some one, groping near the surface and the facts, down where disease germs and cyclones work their mischief, will one day read aright the complex signs of epidemics now incomprehensible.

NASAL CATARRH.[1]

BY HOMER M. THOMAS, A. M., M. D.,
CHICAGO.

The internal covering of the nasal fossæ consists of a mucous membrane called the pituitary, from the nature of its secretion; also the Schneiderian, from Schneider, the first anatomist who showed that the secretion proceeded from the mucous membrane and not, as formerly supposed, from the brain. The mucous membrane is intimately adherent to the periosteum, or perichondrium, over which it lies. It is continuous externally with the skin, through the anterior nares, and with the mucous membrane of the pharynx, through the posterior nares. The mucous membrane is thickest and most vascular over the turbinate bones; it is also thick over the septum, but in the intervals between the spongy bones, it is very thin. This membrane is provided with a nearly continuous layer of branched mucous glands, the ducts of which open upon its surface. Under normal conditions, nasal mucus is very viscid, slightly opaque and strongly alkaline; it always contains some columnar epithelium; its composition is principally water, of which in 1,000 parts there are nine hundred and thirty-three, also, mucosine fifty-three (53), chloride of sodium and potassium five, calcareous and alkaline phosphates three, and some lactate of soda. The smooth, viscid and adhesive character of mucus which forms a coating for the mucous membrane, serves to protect its parts, enables their surfaces to move freely one upon the other, and modifies the process of absorption. It is to a common and very general disease of this mucous membrane, viz.: nasal catarrh, that I wish to call your attention.

The physiology of the nasal passages should as constantly be borne in mind as that of any other structure of the body. Respiration in health is carried on almost exclusively through the nasal passages. The ciliated structures lining these passages serve to arrest the ingress of various irritating substances in the respired air. The surface is covered with a delicate network of blood-vessels, with a large vascular and nervous supply, which raises the temperature of the respired air to a warmth suitable for the throat and lung passages. In an outside temperature of fifty degrees Fahr., the air, in its passages through the nose, is raised to 88°. Any process which interferes with this natural function is a cause of nasal catarrh.

The etiology of this disease is of the greatest importance. A perfect understanding of its causes and mechanism is the goal of the pathologist. From the first cold of the infant, along through the various stages of chronic rhinitis, to define the changes taking place, describe the morbid anatomy, study the causes and observe its course to where we see many manifestations of abnormal action, helps us in directing its hygienic and therapeutic management. And first we may well ask, is heredity a factor in causing nasal catarrh? I think not. In many cases there is a marked coincidence; but not necessarily a related cause. The histological facts concerning cell life will prove a successful contravention to the theory of heredity. The living cell is composed of finely granular matter, called protoplasm.

[1] Read before the Chicago Pathological Society.

The cell has a nucleus which may be round, oval or irregular. In the interior of the nucleus are small bodies, called nucleus corpuscles. In its natural state it develops, on its surface, a membrane. The cell, according to Virchow, has a three-fold vital activity: 1. The nutritive, which displays activity for its own preservation; 2. The formative, showing an activity in its own propagation; 3. The functional, or its behavior in its outward relations to other parts. During the life of a normal cell, under normal circumstances, it displays no other kind of activity. Its component parts render it incapable of any other kind of activity, consequently there are no changes except the physiological ones. Nor can any combination of these three activities result in disease. If the cell maintains its normal surroundings, it will live out its physiological life and disappear according to the laws of its own existence. Nothing can change these activities, except what comes from without. The nature of the surrounding influences over cell life, whether single or joined to others, may be favorable or unfavorable to all of its three activities; but the influence of heredity must come from within, if it comes at all. The law of a cell's life contradicts this. There is no escape from this law. All inside influences are healthful. To some extent a cell is not affected by its surroundings, because of its own vital force; but this range of independence is limited. When the external conditions of cell life deviate from the normal, then disturbances of cell activity ensue and disease occurs. I think a broader interpretation of this law can make it apply to the question of heredity in lung disease, as well as in catarrh. I am satisfied much unnecessary apprehension exists in the minds of many patients on this point. The fact of a parent having phthisis is no tenable ground upon which to base an opinion that the disease is transmitted to the child. It may be a ground for suspicion, especially if the child is living under the same exciting causes as those which developed the disease in the parent. But that is as far as we are physiologically warranted in assigning heredity as a cause.

Inflammation of the mucous surfaces of the nasal passages is due to enlargement of their blood-vessels, and a great increase in their number. This increase is more apparent than real, for these vessels exist long prior to the apparent increase; but as they do not carry red blood corpuscles, they were not visible under the microscope. To permit the red blood corpuscles to flow through the vessels of a smaller caliber, the sympathetic nerves that control the muscles that surround this and other blood-vessels are debilitated. They are in a paretic condition. This condition is due to injury to the sensory nerves, principally by colds, also by other agents, such as tobacco, stimulants, strong irritating applications, etc. Unless the irritation were thus caused, the sensory nerves would not act reflexly upon the sympathetic nerves, causing a paretic condition. Because of this fact, there ensues such phenomena as inflammation, proliferation, hyperplasia, atrophy, œdema and ulceration. Without irritation, inflammation and its sequelæ cannot exist; hence every irritation produces more or less inflammation.

The etiology of nasal catarrh may be either local or exciting, predisposing or constitutional. As exciting causes may be mentioned the following: Getting the feet wet, standing or sitting for some time on a cold surface, exposure to night air insufficiently clad, changing beds from a warm to a damp room, mothers rising at night in the care of children, occupations with much dust, smoking, excessive moisture, sudden changes in the weather, dry, dusty atmospheres, insufficient clothing, slippers, hair clipping, cigarette smoking, mouth breathing, stimulants, etc. Bosworth has said that sealskin sacks have, in a given time, caused more deaths than small-pox. Among the constitutional causes are: rheumatism, malaria, measles, scarlatina, diphtheria, neurasthenia; while excessive fatigue, either mental or physical, by impairing the general health, places the system in a condition favorable to acquiring nasal catarrh.

There are three stages of nasal catarrh: 1, the dry stage, in which there is hyperemia, heat, redness, tumefaction, and pain in the mucous membrane; the mucous membrane being dry and dark-red in appearance; 2, the moist stage, which follows and supplements the first, with transudation of serum and white corpuscles into the connective tissue, cell proliferation, and organization of lymph, while the mucous follicles and glands are enlarged, distended and excessively active; 3, the purulent stage, marked by pathological conditions, denudation of the epithelium and the presence of a raw surface, while the excessive mucous secretion changes to a muco-purulent or pur-

ulent one. The presence of reflex eye symptoms in nasal disease is an interesting feature of it. Cases in which there exists a neurotic affection of the Eustachian tube of the left ear are often markedly relieved by spraying the nasal passage with vaseline. A certain group of eye symptoms, such as lachrymation, photophobia and conjunctival hyperemia, are observed in a number of patients who go to the rhinologist; and yet an examination of their eyes reveals no anomaly. The vision is normal, there is no eye strain, the conjunctivæ are healthy, and the tear ducts open. For such cases relief of the co-existing rhinal affection usually results in the cure of the eye trouble.

An interesting case was recently observed. A lady was troubled with severe hypertrophic rhinitis. The turbinate bones were well cauterized, and then the patient asked for relief for an eye trouble, stating that she had been unable to use her eyes more than five minutes at a time for the last three years. She was referred to an oculist that she might get relief. She returned to the physician's office in two weeks, and stated that she had not been to the oculist, but that the next day after her hypertrophies had been cauterized, she was able to read at night without affecting her eyes. Voltolini demonstrated that asthma may be relived by the removal of nasal polypi.

In the treatment of nasal catarrh the diseased secretion, which is always acrid, should be removed. If morbid growths are present, as they are also a source of irritation, they should be removed, thus checking the local source of inflammation. The new secretion which forms on the mucous surfaces should be prevented from becoming acrid, thus avoiding a recurrence of inflammation. Hygienic and sanative measures should be insisted upon. These prevent a continuance of irritation to the sensury nerves located on the surface of the body, and also to the mucous membranes, by colds and other irritating agents. You thus remove the originating causes of inflammation. Then, *vis medicatrix naturæ* performs the cure, if possible.

The basis of the successful treatment of nasal catarrh, is a thorough application of the principles of antiseptics. Given a case in which it is possible to efficiently medicate the anterior and posterior openings of the nasal passages as often as necessary, and in a great proportion of cases a cure will result. In order to accomplish this end, it is first necessary that the passages should permit a free entrance and exit of air during inspiration and expiration. Anything interfering with this normal function is the starting-point of the development of nasal catarrh. Conditions may exist in the nasal passages requiring surgical treatment, involving the straightening of a deflected septum, or the removal of portions of the superior turbinate bones. If an obstruction exists which interferes with free nasal respiration, there can be no successful treatment until the obstruction is removed. However, in examining the nasal passages, we may be led into the error of suspecting marked obstructions from the tortuous and irregular appearance of the passages upon rhinoscopic examination. It has been estimated that out of six hundred cases there were not over ten which presented perfectly straight and smooth passages. Hence internal deviations of the passages are not a source of disease, provided they do not interfere with perfect nasal respiration. I think a great deal of unnecessary surgery is done upon the nasal passages. It is attempted largely for the purpose of gratifying the ambition of the surgeon, and incidentally of affording some experimental relief to the patient. My experience is that the large proportion of cases do not require any surgical procedure.

The remedies advocated for the treatment of nasal catarrh have comprised almost the whole materia medica. They consist of strong astringents, strong solutions of nitrate of silver applied with a post-nasal syringe, sprays of the tincture of chloride of iron, tannic acid, etc. More extended experience in the treatment of this disease has simplified the treatment. At the outset we spray the nasal cavities with Dobell's solution, or with Listerine. Carl Seiler's antiseptic tablets are very effective. Having cleansed the nasal passages thoroughly we are now ready to apply the medicament. Where there is marked hypertrophy, the galvano-cautery should be used. You can use, about three times a week, a spray of vaseline in combination with tincture of iodine, or carbolic acid. Albolene is also an excellent medicament. Rhinal inflammation invariably commences on the superior and middle turbinate processes, and extends in all directions in the nasal passages and into the passages connected with them, except on the floor of the nasal passages or inferior nasal meatuses. The

under surfaces of the four diseased turbinate processes cannot be thoroughly cleansed or treated by the anterior nasal openings. To thoroughly treat these structures approach must be made by way of the posterior nasal openings. I have found the Starkey tip most excellently adapted to treating these surfaces.

A powder, which has been very satisfactory in its action on the mucous membranes of the nasal passages, consists of one grain each of borate and bicarbonate of soda, three grains of carbonate of magnesia, four grains of cocaine, and a sufficient quantity of the sugar of milk to make one hundred grains. This combination is efficient in allaying acute inflamatory attacks and also in temporarily relieving hypertrophies of the turbinated bones. I use it by insufflation both anteriorly and post-nasally. The physiological action of this powder seems to be due to its stimulation of the vaso-motor nerves, causing contraction of the vessels of the terminal bulbs of the peripheral nerves and diminishing their blood supply.

The local use of the various preparations of vaseline is necessary for the successful treatment of nasal catarrh. I have found useful the following preparations of vaseline: Vaseline pure, vaseline with eucalyptol, vaseline with gaultheria, vaseline with carbolic acid, vaseline with pinus Canadensis. An acute attack of nasal catarrh can sometimes be aborted by the internal administration of a quarter of a grain of morphia sulphate, and one one-hundred and fiftieth of a grain of atropia; in a very severe attack the dose can be increased to half a grain of morphia sulphate, and one one-hundredth of a grain of atropia. However, in spite of all we may do in the way of local medication for this affection, there are at times patients who do not improve as we would like them to do. If the history of such cases is carefully looked into, there will usually be found a diathetic condition at the bottom of the nasal trouble, the relief of which will cause a subsidence of the local inflammation. Thus a catarrhal condition frequently extends into the stomach and intestines, in which we have the combined symptoms of gastro-intestinal catarrh. When the nutritive system becomes deranged there are many sympathetic disturbances which follow.

Each case of nasal catarrh has its specific and special indication for treatment. As a rule, routine practice will not bring satisfactory results. By carefully analyzing all of the exciting causes present in each case, and efficiently directing our remedies to the relief of both general and local conditions, we are warranted in hoping for a successful termination in the treatment of a very large proportion of cases afflicted with nasal catarrh.

ADMINISTRATION OF MORPHINE BY THE NOSTRILS.[1]

BY CARL H. VON KLEIN, A. M., M. D.,
DAYTON, OHIO.

As a rule, where persons dislike the taste of morphia, or where it is desired to have a rapid physiological action, the hypodermic method of administration is resorted to. This method is open to the objection that it requires a small surgical operation and that this sometimes is followed by the formation of an abscess.

I desire now to describe a new method of administering morphia, namely, through the mucous membrane of the nose—a method which has been thoroughly tested by me in over one hundred cases, in which the immediate physiological action of morphia was necessary. I have found it to be reliable and more prompt in its action than the administration of the drug by the mouth or hypodermically. It requires much smaller doses than is requisite in dosing by the mouth, and no larger dose than is usual for hypodermic administration.

The manner of administering morphia through the olfactory canal is simply by causing it to be snuffed up the nasal chambers, in the same manner and in the same way as snuff-tobacco is used. The dose is divided into two equal parts, and each part is placed upon the end of the thumb and snuffed up into the nostril. The membrane being very soft and delicate it appears to be absorbed instantly. I have tried it on myself on several occasions and the absorption seemed almost instantaneous. Fifteen seconds after the introduction of the morphia, I have blown my nose; and nothing could be found in the secretion. However, in poor qualities of morphia, the drug will not be absorbed as readily.

In cases where the nasal chambers are covered by crusts or dry secretion the cavities

[1] Read before the American Rhinological Association, October, 1890.

should be cleansed before administering morphia, care being taken not to snuff it up too strongly. If the drug is of a poor quality it will produce sneezing; but the narcotic effect will be the same.

When morphia is administered in the manner I have just described, it is tasteless, its action is rapid and the narcotic effect lasts for a longer period than when this drug is taken either by mouth or hypodermically.

Foreign Correspondence.

LETTER FROM BERLIN.

Berlin, September 26, 1890.

Reminiscences from the Congress.—Koch's Latest Discovery.—The Emperor Protecting a Physician.—The Prostitute Question.—The Gonococcus.—Onanism in a Child eighteen months old.—The Romance of an Alleged Madman.—Sexual Perversion in the German Nobility.—A Sane Inmate of an Insane Asylum.

The Berlin Congress has done wonders in changing the repute of American physicians abroad. The notorious "Philadelphia Doctor" no longer exists, and those previously regarded as charlatans are to-day viewed with respect and mentioned with terms of high praise. It is at last an established maxim among German physicians that the American practitioner is in every way the peer of any of his European colleagues. Not only the great number of American guests was an immense surprise, but also the quality of the American representatives and the indefatigable energy displayed by them. It is a fact that, while the European physicians visiting the Congress "did" the town, the Americans were hard at work in the sections, hospitals, or at the exhibition. It has also been favorably commented upon that the majority of Americans were accompanied by their wives. The brilliant lecture of Prof. Wood on anæsthesia will probably have a lasting influence upon anæsthetic practice in Germany, inasmuch as many surgeons have concluded to try ether instead of chloroform, which is almost exclusively used in Germany.

The disgraceful scenes at the banquet given by the city of Berlin to the Congress were recently the topic of discussion in Council. A councilman called the Congress a medical schuetzenfest, and emphasized the waste of money. He was not altogether wrong. The money spent by the city for the Rathhaus banquet was really enormous and the result was total intoxication of most of the shining lights of the profession. I regret to state that the bigger the man the more he was inebriated. On a Professor whose name is a household word all over the medical world artificial respiration was practiced for almost an hour and another Professor who has revolutionized one of the most important of medical branches had a bad cut in his head, the result of a fall. A French physician who has made his name renowned by fighting intemperance through exposure of the injury inflicted upon the organism by alcohol, was unable to spell his own name. By a queer coincidence I also saw two men hugging each other who are known as irreconcilable antagonists in science, one a leader of German bacteriologists and the other a well-known Paris Professor who does not believe in bacilli.

Professor Koch is just now experimenting with the new bactericide on the living organism. His announcement at the Congress that he had found a remedy which kills the bacillus tuberculosis without injuring the organism, was received with incredulity, all the more as he suppressed its name. Recent researches established by Koch at the Imperial Health Office appear to demonstrate that the antibacterial agent in question acts in the indicated direction, not only on animals, such as the guinea-pig, but also on man. How long yet and tuberculosis will—according to that outlook—be included among the curable diseases. But who has to-day really the courage to believe that?

At a recent visit paid to Heligoland, which has been reunited with the Fatherland, I learned of an interesting little affair in which the Emperor of Germany assumed the rôle of a doctor's protector. In the proclamation accompanying the annexation of Heligoland, the Emperor had promised not to injure the business interests of any of the residents of the island. Dr. Lindemann, the old resident physician of the island, soon after that found cause to complain to the Emperor that two German physicians intended settling in Heligoland, while the British Government had refused that privilege to any other doctor. Next day Dr. Lindemann received word from the Imperial

Cabinet that His Majesty forbids the settling of a second physician in Heligoland, except on consent of Dr. Lindemann.

The Berlin city authorities are at loss what to do with their twenty thousand registered prostitutes. At present they can room where they please, but are forbidden to walk on certain streets, such as Unter den Linden, Leifzeger and other streets, and are compelled to present themselves twice a week for examination in the City Hall. Their examination, as carried on to-day, is a perfect farce, and consists in the ocular inspection of the genitals by an old doctor, provided with a badly-disinfected speculum. Subacute, chronic or localized gonorrhœa this physician could not possibly discover, and the result is an enormous rise of the number of cases of gonorrhœa in Berlin, although few of the women were found to be infected. The fathers of the city have consequently issued a new regulation, which makes the examining office a position for life, and directs a microscopic and bacteriological investigation in every case.

The question whether the presence of the gonococcus in the genitals of the female is conclusive evidence of gonorrhœa has at present entered into a new and interesting phase of development. For, in a large number of cases this microbe has been found where the suspicion of sexual intercourse was out of the question. Fraenkel and Widmark have shown that in vulvo-vaginitis of little girls the gonococcus is always present. Against this doctrine powerful arguments have been advanced, particularly the manifold and obscure sources of infection in these cases. The lately-published investigations of Vibert and Bordat, appear to fully confirm the doctrine of Fraenkel and Widmark. Six girls aged from two and one-half to eleven years, claiming to have been immorally approached by six men were the subject of examination. The men charged with the crime were likewise examined, but no trace of gonorrhœa was found in them. Singularly in all six girls the gonococcus was found to be present. To be sure, if the gonococcus is present in every case of vulvo-vaginitis, it will be exceedingly difficult henceforth to diagnosticate gonorrhœa in the female, unless manifest evidences are present. And unfortunately it is true that the chronic and subacute cases of gonorrhœa in the female form the most frequent sources of infection. Still the examination of the prostitutes is doing some good and Berlin has fewer cases of gonorrhœa than New York, for instance; though I firmly believe Berlin to be a more immoral place than New York.

That onanism is largely practiced by children is known, but that an infant eighteen months old could be a confirmed onanist is certainly a revelation to the greatest pessimist. Dr. Crivelli, of Paris, presented to the Congress the photograph of a child of the age stated, showing a development of the genital organs like that of a girl of eighteen years. Mammæ and mons veneris were immensely developed, the menses had appeared and continued since three months, and had lasted for from three to four days. To perfect this phenomenal group of appearances, the child was a confirmed onanist, indulging in the act about twice a day.

The immoral tendencies and perverted sexual appetites of some of the nobility of Germany have just now come again to the front in a most disgusting manner. Von Zastrow, a representative of one of the oldest and richest noble families of the land, who was sentenced many years ago for illicit intercourse with men, is the type of this class of criminals.

Yesterday Major Von Normann, Commander of the Potsdam Subofficer's School, was found dead in his room. His radial arteries were opened and he was poisoned besides. Twenty-seven cadets had left the academy, but declined to state the reason for it. At last the revolting practice of the Major had been reported, and all the town knew that he would kill himself, so no one was surprised. I believe that this perversion is simply a certain kind of cerebral affection —a mania, and as such subject to treatment.

Professor Eulenburg, of Berlin, has this week pronounced sane a young Hussar Lieutenant, Carl Hermann, who could write a book on his troubles. He was thirty years of age, rich, handsome and happy, when suddenly, owing to family intrigues, he was taken from the Austrian garrison, where he served, and sent to an Insane Asylum. Four times he succeeded in escaping, but was recaptured each time. His wife was at the bottom of his misfortunes; she had, for example, charged him with practicing abortion on her person. While in the Asylum the young officer wrote "A ball-night in the Insane Asylum," and made plenty of money by the immense sales of that book, obtaining thus the means for escape. On the testimony of Prof. Eulenburg the officer will

be reinstalled into his former titles and possessions.

PERISCOPE.

Rabies or Hydrophobia.

A discussion at the Neurological Section of the New York Academy of Medicine.

The President of the Section, DR. L. C. GRAY, in discussing the clinical aspects of hydrophobia said that the extreme variability in the period of incubation had given ground for the belief held by many competent observers, that if there really existed such a disease as hydrophobia at all, death might also occur, as the result of fear, with symptoms closely resembling the true disease. He thought himself justified in assuming that frequent mistakes are made in the diognosis of rabies, the so-called dumb rabies being merely a symptom of simple purulent meningitis and meningo-encephalitis, and that very few cases of true rabies or hydrophobia—the latter term being used to signify the disease in man—had been observed in New York City or in the country at large, and he believed that there was a disease running a fatal epizoötic course in the dog and other lower animals, capable of being communicated to the human being, and causing death, although the evidence of this would rest mainly upon pathological and experimental findings.

DR. L. C. DANA said that there was no constant change to be found in this disease. The nervous centres, which are the parts chiefly involved, are congested and occasionally showed hemorrhagic and softened spots, with subsequent evidences of increased vascular activity, exudation of leucocytes into the perivascular spaces and possibly the beginning of a multiple focal myelo-encephalitis or of focal necrosis and the symptoms are evidently not the result of any organic changes in nerve tissue, but of a distinct poison, the product undoubtedly of microbic activity. In the light of Pasteur's scientific work this question of specific origion was proven. The speaker did not believe that there were authentic clinical records of a single case in which the fear of hydrophobia had caused a disease measurably similar to rabies, nor was there a case of death from this hypothetical phantasm. There had possibly been some tetanus following bites or acute mania, in those predisposed, from fright. He thought Pasteur had demonstrated the fact that as a reliable prophylactic measure, antirabic inoculations could be successfully employed.

DR. H. M. BIGGS then gave an elaborate description of the respective methods of inoculation and of the various emulsions used in the work of both Pasteur and Ferran.

DR. H. C. ERNST, of Boston, who has done considerable experimental work in this field of inquiry said that he regarded the results by Pasteur as among the greatest achievements of modern medicine. The speaker had been entirely converted to a thorough acceptance of the theory after conducting a series of inoculation experiments. If there was one thing certain in medicine, it was the unerring precision in the results obtained by the inoculation with these cord emulsions under the dura mater of the healthy rabbit. There is nothing like it in the whole range of scientific experimentation. As to the existence of a constant lesion, pathognomonic of rabies, he did not know that this could, at present, be defined with scientific accuracy, but careful observation had demonstrated the very uniform presence of infiltration of the minute vessel walls in the medulla with white cells, engorgement of the veins, and occasionally perivascular hemorrhages. What appeared like small miliary abscesses were also present. The condition had been aptly covered by the term "miliary bulbitis." Dr. Ernst then gave the clinical histories of three cases of true rabies in man which had come under his own personal observation, and which, taken with the fact that a large number of dogs were affected at or about the same period, pointed to the recent existence of an epidemic of rabies in Boston. One of the cases, cited in detail, was of special interest, because the patient, between the paroxysms, was able to describe his condition. He had been especially questioned as to whether there existed any repugnance to water, and had positively stated that this was not so, but that any mental process connected with the act of deglutition caused an uncontrollable spasm of the muscles of the throat, and this patient had also described himself as perfectly conscious of his acts during the violent paroxysms, but as being utterly unable to control himself. Even while thus quietly describing his sensations the fit would come on, and the next moment he would be on

the floor, struggling with four or five men. Then as to the value of the preventive method, the speaker instanced the case of a boy who was bitten in August by a dog which, within fifteen minutes, had also bitten several dogs, and of these, two had died of rabies, and the father of the boy, becoming alarmed, had consulted the speaker. Inoculation was advised, and was submitted to twice a day. No bad symptom had resulted. Before the boy's return home, a third dog had succumbed to unquestionable rabies.

Whether there was anything in Pasteur's claims or not, one thing was certain, he had got hold of a specific virus which could be transferred from one animal to another indefinitely, always producing a sequence of practically identical symptoms. The experiments made by Dr. Spitzka had not been carried far enough. They had produced something similar to the appearance of rabies in the rabbits, but had offered no sort of ground for comparison with Pasteur's experiments. While hardly wishing to stand up as a champion of the Pasteur method, if the statistics of the Institute were not reliable, he was still bound to believe in the honesty in purpose of Pasteur and his assistants. It was a significant fact that after the careful elimination of all cases in which an element of uncertainty existed the mortality rate for those treated by inoculation under the method was only ninety-eight one-hundredths of one per cent. He expressed surprise at the statement that there could be no such condition as pseudo- or lysso-phobia.

Dr. R. W. Birdsall said he had seen a number of cases of pseudo-rabies resulting from fright after a bite or scratch of a dog. These cases had not resulted in death, though he was not prepared to go so far as to say that death from fright was not possible. The nervous shock sustained might set up a series of changes such as motor paresis, œdema of the brain and coma, resulting in death. He did not believe they were yet in a position to be able to refer the phenomena of true rabies to the existence of one kind of specific germ. The effects might be due to the presence of distinct varieties.

Dr. H. P. Loomis had only considered the subject from a pathological standpoint. The findings tallied very much with those described by Dr. Ernst. Sections of the lower portion of the medulla had showed congestion of the capillary vessels and giant cell infiltration of the adventitia, but no capillary hemorrhages or thrombi.

Dr. Byron, who has made extensive experiments at both the Carnegie and the Loomis laboratories, had arrived at the conclusions that, (1) inoculations of the specific virus of rabies under the skin are completely useless, (2) the results desired could never be produced by any process except subdural inoculation, and that even then the effect was not inevitable. The question was a serious one, and the subject still open to further experimental research before any definite scientific conclusions could be formulated.

Dr. E. C. Spitzka said he had made no experiments on rabbits as intimated by Dr. Ernst, who had evidently not followed the points of his work. In the experiments made by him on dogs, he had made no claim that these animals had represented true cases of hydrophobia, but by the introduction of various irritating substances into the brains of these dogs he had produced conditions of bogus hydrophobia. He was now associated with the conduct of a series of elaborate experiments on rabies the results of which could not as yet be formulated.

Dr. L. C. Gray thought the discussion had proved, (1) that there is undoubtedly in the lower animals a disease, known as rabies, possibly made up of several diseases, due to different micro-organisms; (2) that this disease is more frequent in the lower animals than a similar disease in man known as hydrophobia; (3) that while this so-called rabies in animals occurs very often in this country, it occurs less frequently in the human being; (4) that very few medical men have seen genuine cases of hydrophobia; (5) that cases of pseudo-hydrophobia are by no means uncommon, and that death could result from the condition; (6) that there still exists considerable diversity of opinion as to the value of Pasteur's method which would furnish material for discussion and incite to further experiment.

Exsection of Part of Pubic Bone.

The *Centralblatt für Chirurgie*, July 26, 1890, quotes the following from the *Gaz. des Hôpitaux*, 1890, No. 33.

In the case of a soldier, twenty-three years old, with pain in the left inguinal region and in the upper part of the thigh, Moty found a

flat, hard, elastic, fluctuating, irreducible, non-pulsating tumor, beneath the aponeurotic structures. A large cheesy abscess, with fragments of bone, was exposed by operation. The left half of the symphysis pubes was converted into a tuberculous sequestrum. This was removed, together with all caseous matter and a counter-opening was made in the perineum. The urethra and spermatic cord were carefully protected. Urine was voluntarily passed three hours after the operation. Recovery took place in five weeks. Moty's operation shows that the symphysis pubes may be removed in part or entirely without injury to the urethra, and the spermatic cord may be protected from all injury, on account of its mobility. A counter-opening in the perineum provides for antisepsis and drainage.

In the case reported the origin of the tuberculous process is unknown. There was no history of trauma. The testicle and the urethra were healthy; and, although the tuberculosis must be recognized as a local manifestation of a general infection, the operation was followed by excellent results.

Cincinnati Medical Schools.

It is a gratifying fact that all the regular medical colleges of Cincinnati have kept step in the march of progress in the matter of extending the curriculum. The announcements all state that the three-term course has been made obligatory, a statement which might have been anticipated for years from the fact that all three of the colleges have been placing a premium upon the extended course by abating the fees for the third year. We are informed that the final concert of action was without conference but because each of the faculties recognized that the time was ripe for the change.

A wholesome tendency is shown by the fact that all the schools are remodeling their buildings with reference to clinical and laboratory facilities. This is a move in the right direction and points infallibly to the time when the present order of things will be reversed in medical teaching. It points to the time when the demonstrator will supplant the lecturer, and when the practical teacher will take the place of the didactic "professor." It indicates the time when the Pestallozian principle of education shall dominate medical pedagogues; the time when things rather than words, objects rather than phrases, shall be taught in the medical college.—*Cincinnati Medical Journal*, August, 1890.

Digging up Streets.

Dr. C. N. Dowd, of New York, has been studying the influence on health of digging up the streets of cities, and has published the results of bacteriological experiments in this direction in the *Medical Record*, June 21, 1890. He estimated the number of bacteria in 1 c.c. of the soil taken from different places. Sixteen of these samples were taken from where the earth had a strong odor of illuminating gas, and an equal number from where there was no such odor. The average number of bacteria present was about the same in the two classes of earth. He next studied the action of illuminating gas upon the bacteria of earth and upon the typhoid bacillus. The results were negative so far as could be determined. He concludes that the digging up of streets may increase the spread of disease-germs, but that the increase cannot be very dangerous. If this be true the digging of ditches in cities ought not to cause great alarm.

Cœliac Affection in Children.

The *Dublin Journal of Medical Science*, September, 1890, says that Dr. R. A. Gibbons, in a detailed description of four cases of what Dr. Gee calls the "Cœliac Affection" in children, thus sums up its general characters: The disease is characterized by the passage of large, loose, white, or whitish, frothy, intensely fetid motions; by pallor of the skin; wasting; loss of muscular sense, and by the fact that it is most frequently met with in children between one and five years of age. The youngest child I have seen attacked with it was between ten and eleven months old. I have seen it in children with perfectly healthy parents, and, indeed, sisters and brothers in every way healthy. In only one family can I trace any history of struma on the side of the father. No history of tubercle can be traced in the family of any of the patients whose cases are related, except one, and in that consumption occurred in a paternal uncle of the patient, and in all there is no history of syphilis obtainable, and no reason to suspect it. In most of the cases there is

a history to be obtained of gout, either on the side of the father or mother, or in distant relations. The examination of the feces themselves throws no light upon the matter. In those I have submitted to careful microscopical examination I have never been able to discover anything abnormal, and I have failed to detect any tubercle bacilli, although they were carefully searched for.

Contagion of Diphtheria at Funerals.

Dr. E. H. Bartley, of the Long Island College Hospital, says, in the *Brooklyn Medical Journal*, September, 1890:

The public at large seem to require very startling results in order to become educated in sanitary matters. The fact that contagion may be spread by corpses does not, even yet, seem to have taken possession of the public mind. Dr. Baker, of the Michigan State Board of Health, has issued a circular calling attention to a case of diphtheria in Lapeer County, Michigan (described in the REPORTER, August 2, 1890, p. 146), which originated from exposure in viewing the remains of a woman and child, brought from another county, and who had died from a throat disease, supposed to have been diphtheria. Many others, says Dr. Baker, would probably have been exposed except for the action of the local health officer, Dr. Wisner, who, suspecting the cause of the deaths to have been diphtheria, warned the neighbors and forbade the opening of the coffins at the funeral. He promptly isolated the first person attacked, and no epidemic followed. This, says Dr. Baker, is quite different from the result of a similar occurrence at Zanesville, Ohio, last spring, where many deaths resulted from exposure to a corpse brought from Chicago. It shows the importance of notice to the local health officer of the arrival of a corpse known to have died of a contagious disease, so that he may take every precaution that may be necessary.

Hysterical Muteism Cured by Hypnotic Suggestion.

M. Ruault reported at a recent meeting of the French Society of Otology and Laryngology (*Revue de Laryngologie*, September 1, 1890), an interesting case in which he cured a woman of hysterical speechlessness by hypnotic suggestion. During a laryngoscopic examination, he drew her tongue out very strongly, and at the same time pushed the mirror back in the throat: he then let go of the tongue, drew the mirror out and said, positively, to the patient: "You can speak now; you are cured. What made you mute was that the bone which holds up the larynx was a little dislocated, but I have been able to set it right by pulling on your tongue." The patient immediately began to speak, with a little hesitation at first, but soon very naturally.

Several months afterwards this same patient became aphonic in consequence of bilateral paralysis of the adductors. Dr. Ruault tried the suggestion again, and also electricity, but neither did any good. Dr. Ruault points out the marked difference shown in this case between the effect of suggestive therapeutics upon a disease depending upon a psychic case, and that depending upon a material alteration in the organs of speech.

Phthisis in Berlin.

According to Dr. George Meyer, in the *Allgemeine Medicinische Central Zeitung*, July 26, 1890, official statistics disclose that the number of deaths from phthisis (excluding laryngeal phthisis and pulmonary hemorrhage) in Berlin, between the years 1880 and 1889 was smallest in the year 1881 and largest in 1889. The mortality, however, in proportion to population has decidedly, though not regularly, decreased. From 1880 to 1889 there were 322,192 deaths in all, of which 41,608—12.91 per cent.—were due to phthisis. Dr. Meyer concludes that the time is ripe for the discussion of the question of establishing institutions for the treatment of diseases of the chest.

Posthumous Labor.

The newspapers reported from Vienna on September 19, that the body of a woman named Goeda was exhumed at Szegedin that day for the purpose of an autopsy. When the coffin was opened it was found that the woman had been buried alive and that she had given birth to a child in the coffin.

This story comes so soon after the account published in the *Lancet*, and repeated in the REPORTER, October 4, that it may be suspected to be a reproduction of that one.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

TREATMENT OF EMPYEMA.

The treatment of empyema has been a moot question since the days of Hippocrates. At different periods in the history of medicine varying meanings have been applied to the word empyema. It has been defined as a collection of blood or of pus or of other fluid in some cavity of the body and particularly in that of the pleura. It has also been used as a synonym for thoracentesis and for the spontaneous evacuation of a purulent pleural effusion, empyema necessitas. To-day, however, by empyema is meant a collection of purulent fluid in the pleural cavity.

An interesting and important discussion on this subject took place before the Ninth Congress for Internal Medicine, at Vienna, April 15 to 18, 1890. The report of the proceedings, compiled by Alexander Fraenkel, is published in the *Centralblatt für Chirurgie*, July 26, 1890. Immerman and Schede read papers on the subject, addressing themselves more particularly to the treatment. For this the main indications are: to remove the pus; to prevent re-accumulation; and to restore as nearly as possible the normal anatomical and physiological relation of the respiratory apparatus. It is generally agreed that pus should be removed as soon as it has been recognized to have formed, in the pleural cavity as well as in any other situation. Such effusions are rarely absorbed. Absorption is said to take place in so-called metapneumonic empyema, characterized by the presence of the pneumonia coccus exclusively. The diagnosis of this condition can only be made by the methods of bacteriological isolation and culture.

The operative removal of pus from the pleural cavity is not very difficult. The prevention of its re-accumulation, however, is a rather more serious matter. As long as any of the excitants of suppuration are left behind, accumulation must recur. The great difficulty is in the removal of all offending matters.

For a perfect result the restoration of the normal respiratory conditions must be attained. This is the greatest difficulty. When there co-exists irreparable disease of the lungs, as in phthisis, in perforative pyopneumothorax or old and neglected empyema, a relative cure—that is, recovery with deformity—is all that can be expected.

Various means have been suggested to meet the indications. The effusion can be removed by puncture and aspiration, but then it usually re-accumulates. This may, however, answer as a palliative measure in desperate cases in which radical treatment is not admissible. Disinfectant irrigation following aspiration is not more successful. A more rational method appears to be irrigation of the pleural cavity by two openings at opposite points (one in front and below, the other behind and above) by means of a

permanent drain which can be closed at times—the method of Michael. This avoids the formation of a pyopneumothorax and suffices for the constant evacuation of the pus. The so-called radical methods all have in common a large opening, remaining unclosed until cure finally results. Since the general application of this principle to the treatment of empyema the mortality has fallen to one-fourth or one-fifth of what it formerly was. Even in putrid empyema the prognosis is no longer as grave as it was and is regulated more largely by the constitutional condition and by complications than by the mere existence of the effusion.

The radical method of treating empyema was not unknown in the days of Hippocrates, nor was the preference for the low opening unrecognized. The method now preferred is that of König, which consists in incision at the side of the chest, sub-periosteal resection of a rib, clearing the pleural cavity of coagula, drainage and antiseptic occlusion bandage. Subsequent irrigation becomes necessary only if the pus becomes stagnant. To avoid the necessity for irrigation, Küster recommends, in case of small, sacculated empyemas, packing the cavity with iodoform gauze; in case of more extensive effusion, an opening and a counter-opening, anteriorly and posteriorly, at the lowest possible points, close to the diaphragm, with resection of a rib posteriorly, to afford thorough drainage.

Brilliant as the results of radical operation undoubtedly are, deformity and impaired function are apt to follow. The lung becomes adherent to the chest wall, which undergoes retraction. By the method of Bülau the production of an artificial pyopneumothorax is obviated, positive pressure being substituted for negative. The principle is that of the syphon. A trocar is introduced at a dependent point on the lateral aspect of the chest. Through the canula a drainage-tube is passed into the thorax, the canula is removed and the drain is made air-tight, and connected externally with a long tube dipping into an antiseptic solution. Constant negative pressure is thus exerted, there is no accumulation and the lung expands naturally. If the lung is readily and completely expanded, as in recent empyemas, this suffices; otherwise, and when the pus is thick, the action may be aided, temporarily or permanently, by aspiration. So, too, if the tube become occluded by coagula, these may be pushed back into the pleural cavity, there to undergo disintegration and liquefaction. The amount of secretion diminishes; it soon becomes serous. The tube is gradually shortened and finally, with the cessation of the discharge, is removed. The cure is complete; there is no deformity, no defect; and the lung is able to move with almost normal freedom. Immerman has collected fifty-seven case treated by the method of Bülau. Of these patients, three died; five required secondary operation; the remaining forty-nine recovered completely.

Schede prefers incision and resection of a rib. He avers that open pneumothorax does not hinder expansion of the lung. As to the question of amyloid degeneration and tuberculosis, as contra-indications in operation, he cites a case in which amyloid disease of the liver, with ascites and anasarca, receded after extensive resection of the chest wall. The empyemas of tuberculous subjects, if the general condition permits, should be treated like all others; but empyemas resulting from miliary tuberculosis of the pleura and from perforation of cavities should be treated only palliatively by aspiration. In ten cases of pyopneumothorax of excessive degree, in which the lung was pressed against the vertebral column and fixed by adhesions, Schede made a flap of the soft parts of the lateral and adjacent anterior and posterior aspects of the chest, resected the underlying ribs from the second to the lower level of the pleural cavity and from the costal cartilage to the tubercle of the rib, removing bone, intercostal structures and thickened pleura; after which he covered

the wound with the original flap. In none of the cases had the condition existed for less than three years. Six of the patients were cured; one died in ten days, of iodoform intoxication; in one Bright's disease developed; and in two recovery was not complete at the last observation.

In conclusion, we think the present opinion to be that as soon as effusion in the pleural cavity is recognized as purulent it should be evacuated. Puncture and aspiration, with or without irrigation, may be done as a palliative or preliminary measure, and Bülau's method of aspiration drainage may be tried in all other cases. In double empyemas its application is almost indispensable. Other methods failing, recourse may be had to incision and resection of one or more ribs.

INSOMNIA OF CHILDREN.

The treatment of insomnia of children is one of the most important subjects which come under the attention of medical men; for, while at times insomnia is not a very serious matter, many times it is very serious to both children and parents. In discussing the treatment of insomnia, Simon, as quoted in the *Revue Médicale*, July, 1890, dwells upon the importance of searching for the cause, which is often very difficult to discover. Most frequently insomnia is caused by dyspepsia; and it is important to question parents as to the manner in which a child is fed, and to investigate the milk of the nurse, to see if starchy food has not been given too early, or even alcohol or possibly tea or coffee. Sometimes insomnia depends upon the fact that the evening meal is too large. Children as old as three or four years should not eat too much in the evening immediately before sleeping.

When the cause of insomnia has been discovered, the first duty of the physician is, of course, to do away with that. After this, hypnotics may be required; and, of all hypnotics, Dr. Simon truthfully says, opium is the very best. He says an attempt has been made to banish the use of opium from the therapeutics of infancy, but that this is entirely wrong. It would not be proper to give opium to a child suffering with constipation or disorder of the kidneys; but in the absence of such contra-indications, laudanum may be prescribed in the dose of a half-drop under one year, and of a drop for each year after that. Syrup of codeine is a good hypnotic, and is admirably borne by little children. Half a coffeespoonful may be given under one year, and a spoonful for each year afterwards. The bromides are often useful, four or five grains at six months of age, seven or eight at a year, and afterwards fifteen grains at a dose in the evening. Chloral is an excellent hypnotic, and Simon says it is devoid of danger in the same doses as are recommended for the bromides. Simon advises that it be given preferably, in a lavement, using first a simple lavement to wash out the bowel, then the chloral, combined with camphor or musk, in the yolk of an egg, stirred up with a little quantity of water. He thinks that chloral is especially adapted to children who are threatened with convulsions, hiccoughs and jerkings. In some cases antipyrin, used in the same way as chloral, is a good medicament.

These suggestions are very interesting as coming from a man of great ability and much experience, and especially because they do not consist in theoretical studies of this troublesome difficulty, but propose plain and practicable measures for curing it.

COLORED SOUND.

In the *Revue de Laryngologie d' Otologie et de Rhinologie*, September, 1890, there is an exceedingly interesting article by Suarez de Mendoza upon the curious subject of color perceptions associated with sound, which has been spoken of editorially in the REPORTER, January 28, 1888, and November 16, 1889. His communication is an abstract of a more complete work which is to be published very soon. He discusses principally what he calls false or pseudo-sensations

of color sound, of which he gives a number of illustrations from his own observation. In concluding, he discusses the reason for the various sensorial associations of this kind. Some authors have tried to discover it in the relations of location of the sensorial centres of the brain and of anastomoses between the nervous fibres or in the reciprocal vibrations of their cells. If we accept the theory of anastomoses, it it will be necessary to admit that the brain-cells, as well as the sensorial centres, have anastomoses, which in most persons are rudimentary, but in particular persons are well developed, either spontaneously or as a result of special cultivation. It is possible that secondary sensations may be produced by a reflex irritation action through the sensitive branches of the pneumogastric nerve, as seems to be indicated by experiments made five years ago by Urbantschitsch.

These different theories do not thoroughly satisfy Dr. Mendoza, and until some more complete explanation is suggested, he prefers to attribute the phenomena which he has studied to an association of ideas—conscious or unconscious—dating from childhood. In this category, he would place the occurrence of ideas of color connected with days of the week and periods of history. Some of these experiences he is disposed to attribute to some peculiar psychic operation, the intimate nature of which has not been discovered.

RABIES OR HYDROPHOBIA.

At the last meeting of the Neurological Section of the New York Academy of Medicine, a very interesting discussion took place on the subject of rabies or hydrophobia. This discussion is published in the department of "Periscope" in this number of the REPORTER, and will, no doubt, prove instructive to its readers. In commenting upon it, it must be said that the moderate tone of most of those who took part in the discussion, as reported, must be gratifying to all who desire that right views shall be reached in so important a matter.

Dr. Ernst, of Boston, spoke of the "unerring precision" in the results obtained by the inoculation with cord emulsion under the dura-mater of the healthy rabbit. Those who are familiar with the facts of Pasteur's experiments and the reported results of Dr. Ernst's own experiments, will probably think this expression is too strong. The term "unerring precision" can hardly be applied with propriety to results which so often vary from a standard which Pasteur has repeatedly declared to be infallible.

It is not very likely that those who hold positively to the specific theory of hydrophobia, and those who do not believe this theory, will be of one mind in the near future; but temperate discussions of the subject must lead to improvement in knowledge in regard to it, and ultimately, we may trust, to the general acceptance of accurate and trustworthy beliefs.

DR. BARTHOLOW AND THE JEFFERSON MEDICAL COLLEGE.

On October 27, the Trustees of the Jefferson Medical College declared vacant the Chair of Materia Medica, General Therapeutics and Hygiene, which for eleven years past has been occupied by Prof. Roberts Bartholow.

This is the culmination of a long and somewhat painful process, during which it has been openly stated in the newspapers and elsewhere that Dr. Bartholow was suffering with impairment of his mental faculties. Some weeks ago the Trustees of the Jefferson Medical College gave Dr. Bartholow an opportunity to resign his chair, or to take a leave of absence for about six months, in order that he might see if it were possible to recuperate sufficiently to resume his professional duties. This opportunity Dr. Bartholow declined to accept, asserting that it was a reflection upon his mental and physical condition, and that he was entirely com-

petent to continue to discharge his professional duties.

At one time the students of the College took such a view of the case that they held a meeting and adopted resolutions, praising Dr. Bartholow very highly, and requesting that the trustees should recognize his ability as a professor and continue him in the chair of Therapeutics. Since then, we understand, the students have recognized the wisdom of the action of the Board of Trustees and are quite in accord with it.

It is to be hoped that—notwithstanding he is so reluctant to accept it—the opportunity for rest, which will be afforded to Dr. Bartholow, may be utilized to the establishment of his health, and that the Jefferson College may not suffer in any way by his removal from the Faculty. Already a number of candidates for this very desirable position have appeared in the field, and no doubt others will be heard from before long.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

A MANUAL OF ANATOMY FOR SENIOR STUDENTS. By Edmund Owen, M. B., F. R. C. S., Surgeon to St. Mary's Hospital, London, etc. With numerous illustrations. Small 8vo, pp. viii, 526. London: Longmans, Green & Co., 1890. Price, $3.50.

The author of this excellent book states in his preface that the present volume is the outcome of his desire to leave a permanent record of his work as Professor of Anatomy at St. Mary's Hospital Medical School, from which position he has recently retired after a service of twelve years. One's first thought on seeing a new book on Anatomy is, what excuse can there be for its publication? There has been less progress in this science than in most others, because there has been less room for it. What is found in certain regions of the body is a matter of fact, is at all times capable of proof or disproof. In this respect anatomy differs from physiology, in which the functions of the parts are to a degree matters of inference and conjecture. But, notwithstanding the existence of many excellent books on anatomy, the present one is not superfluous, but it is just what many advanced students need in order that they may profit by their lectures upon surgery and by their practical work in hospital wards, both medical and surgical. The author has designed to give the senior student who has left the dissecting-room a manual which shall supply him with such anatomical information, free from wearisome detail, as is essential for successful and intelligent work in the medical and surgical wards, and in the special departments of a hospital. Thus we find, under a description of the pleura, an account of pleurisy, hydrothorax, empyema, and pneumothorax, with brief statement of the essential points in physical diagnosis, and directions as to tapping the chest. The student is taught how to mark the limits of the lungs, liver and heart, and how to conduct a physical examination of the chest. So, under an account of the spinal cord, the various lesions and their physical characteristics are indicated. In this way there is brought home to the student in an unmistakable way the close connection existing between anatomy and the diagnostic part of clinical medicine. Every student will do well to read certain parts of the book before presenting himself for examination in physical diagnosis. We cordially recommend it, and feel that Mr. Owen has done a real service in writing it.

DUST AND ITS DANGERS. By T. Mitchell Prudden, M. D. 16mo, pp. 111. New York & London: G. P. Putnam's Sons, 1890. Price, seventy-five cents.

Dr. Prudden means by dust, the fine particles of earth and other matters which float in the air or are readily raised and wafted by it, but especially the finest dust, which is visible only when illuminated by a sunbeam. This dust, he says, consists of fine vegetable and animal fibres, such as cotton or wool, and of a great variety of micro-organisms, either single or in masses He aims to point out the sources of these germs and their general behavior, to show the differences between in-door and out-door conditions, and, finally, to suggest measures by which pure, wholesome air can be obtained The disease to which he gives especial attention is—as might be expected just at this time—tuberculosis. This he believes is spread by inhaling tubercle bacilli in the dust of the air, the bacilli getting into the air through the drying and pulverizing of the expectorations of consumptive patients. To prevent this source of infection, he adopts and repeats the recommendation of Cornet—that the sputum of phthisical patients should be collected in cups and burned, and should on no account be received upon fabrics or deposited upon the ground or in ordinary cuspidors.

Those who may be disposed to differ from Dr. Prudden in his conclusion that the tubercle bacillus in the air is such a fruitful cause of consumption, will yet endorse everything he says regarding the simple furnishing of living-rooms, and the recommendation that they should be swept with the windows wide open, and then when the dust has had time to settle, "dusted" by wiping the floors and furniture with mops and moist cloths. This is cleanliness, and cleanliness is the most effective precaution against all septic diseases, medical or surgical.

The book is for laymen, and intelligent laymen will read it; but, unfortunately, its usefulness is necessarily limited by the fact that those who need its instruction most, rarely read anything but a newspaper.

Literary Notes.

—The November number of *The Sanitarian* will begin the publication of the "Transactions of the American Climatological Association," held at Denver, Col., September 2–4, 1890. New subscribers for *The Sanitarian* for 1891, sending their subscriptions before the 15th of November, will be supplied with the November and December numbers gratis. The editor and publisher is Dr. A. N. Bell, Brooklyn, N. Y.

CORRESPONDENCE.

Treatment of Measles.

TO THE EDITOR.

Sir: Noticing that Dr. Hiram Corson referred to your Editorial on Measles, I am induced to write this; for I look upon him as one of the most sensible physicians the world has produced. On reading your Editorial immediately after it appeared, I thought it was strange you should advise such treatment in measles.

Like Dr. Corson, I want my patients kept comfortably cool, in a cool airy room, and to have all the cold water, butter-milk and lemonade they can drink. This is the sum and substance of my treatment in a simple case of measles. When complications appear (which is very rare, when the above course is pursued), of course the proper remedies must be added. Complications I have generally found result from giving hot drinks and keeping the patient too hot.

What a pity that such men as Dr. Hiram Corson could not live to be a thousand years old. The world has too few of them. It is seldom we have the opportunity of reading after men with such good, hard, common sense.

Yours truly,
L. L. SILVERTHORN.

Charleston, Ill.

QUESTIONS AND ANSWERS.

[In this department will be published questions on any medical subject by readers of the REPORTER, and answers by the EDITOR or by other readers.]

Esmarch's Painless Cancer Powder.

DR. JOHN J. TAYLOR, of Memphis, writes:

Will you be so kind as to give me the formula of Esmarch's Painless Cancer Powder?

[Professor Esmarch gave the formula of a powder which he said was exceedingly efficient, and yet painless, in a paper read before the Sixth German Surgical Congress, which was published in the 6th volume of the *Verhandlungen der Deutschen Gesellschaft für Chirurgie*, Berlin, 1877. The formula is on page 208 and is as follows:

℞ Acidi arseniosi
Morphiæ muriatis . . . . . āā 0.25
Hydrargyri chloridi mitis 2.00
Gummi arabici pulveris 12.00

This formula would be represented by the following:

℞ Arsenious acid . . . . . 10 grains
Muriate of morphia . . . . . 10 "
Calomel . . . . . 80 "
Powdered gum arabic . . . . . 1 ounce.]

Dr. Shakespeare's Report on Cholera.

DR. D. W. C. LAVERTY, of Middletown, Pa., asks "Has Dr. Shakespeare's report to the Government on Asiatic Cholera ever been printed and distributed by that office"?

[Dr. Shakespeare's report has not yet been issued by the Government. Inquiry of Dr. Shakespeare as to when it will come out, has elicited the following under date of October 19: "I am now reading the proof of the last chapter of my Report and expect to finish it this week. The Report will make a volume of 900 pages quarto."]

NOTES AND COMMENTS.

Excision of Twenty-six Inches of the Ileum.

In the *Occidental Medical Times*, September, 1890, Dr. J. S. Wintermute, of Tacoma, Wash., reports the case of a man 21 years old, who, on October 5, received a wound from the bullet of a 44-caliber revolver. The bullet entered the back about one and a half inches to the left of the spine, struck the transverse process of the second lumbar vertebra, passed through the abdominal cavity, the anterior abdominal muscles, and finally lodged under the skin in the superficial fascia, about two inches to the left of the umbilicus. Dr. Wintermute first saw the patient shortly before midnight, and about an hour after the receipt of the described injury, when he was in a condition of nervous collapse, and vomiting blood freely. Owing to the absolute want of the necessary operating facilities under which to operate immediately, he was made comfortable for the remainder of that night.

Early the succeeding morning, at about nine o'clock, assisted by Dr. John F. Beardsley, Dr. Wintermute first removed the bullet, and then proceeded, under antiseptic precautions, to perform median laparotomy. Upon entering the abdominal cavity, a large amount of clotted blood, undigested beans, and grapes in their entirety, with chylous material, were met with. The ileum was

found to have been punctured by the bullet seven times in twenty-six inches of its length. In two of these instances the ball had completely severed the caliber of the intestine. So mutilated did this portion of the intestine appear when exposed, that it was immediately decided to amputate it. The mesentery was first ligated with a series of carbolized catgut ligatures, and then divided between the point of ligation and the margin of the gut. After the gut was removed, the upper incised end was carefully placed within the lower, and united with five closely placed interrupted catgut sutures, as suggested by Jobert. The abdominal cavity was then thoroughly sluiced out with hot water, and the abdominal wound sutured and antiseptically dressed. Little blood was lost considering the gravity of the operation, and the patient rallied fairly well after its termination. At five o'clock the same evening he seemed to be suffering little or no pain; however his case was practically a hopeless one, and even under the administration of stimulants he gradually failed, dying at about nine o'clock the evening of operation.

An interesting point in the foregoing case was the fact that so many punctures of the intestinal wall were made in so short a length of the intestinal tract. The entire tract was carefully examined, yet in no place was it injured except within the twenty-six inches exsected; even the mesentery remained intact, except at one point, where the bullet had penetrated it at the margin of the gut, admitting it within the exsected portion. An earlier operation would undoubtedly have afforded the patient greater opportunity of recovery. His loss of blood through hemorrhage into the abdominal cavity, and by vomiting, prior to the time set for the operation, would not have been so great. The nervous shock which he was suffering from after receiving the wound would probably not have been materially augmented, and greater economy of his rapidly failing strength would have been possible under immediate surgical interference.

The Age of Puberty of Indian Girls.

Dr. A. B. Holder, of Memphis, Tenn., says in the *American Journal of Obstetrics*, October, 1890, that the age of puberty among Indians it is not easy to learn, since it is the custom in most tribes for the girls to marry before the menses appear. A curious result of this custom came under his observation while in medical charge of a tribe in the Northwest. Since the girl menstruates after marriage and its attendant pleasures, the idea prevails in the tribes that the menstrual flow is the result of sexual intercourse. In two instances Indian men came to me with the complaint that their daughters, in the boarding-school at the Agency, had been seduced, as their menses had appeared! Girls in the camp will conceal and deny the flow if it occurs before they have been sold in marriage.

It is presumable that the early marriage and consequent sexual excitement, with the entire absence of modesty in Indian thought and conversation, would tend to cause precocious menstruation, and facts establish this impression. Even in the girls who are in school till after puberty menstruation occurs earlier than among white girls in the same latitude.

In St. Xavier Mission School, on the Crow Reservation, Montana, containing forty Indian girls, there are none above twelve years of age who do not menstruate. The St. Ignatius Mission School, Flathead Reservation, Montana, contains three to four hundred Indian children, received into the school so young that the ages of the girls can be learned with considerable accuracy. The sister-superior of that institution says that "in general the Indian girls begin to menstruate younger than the white girls, and those who at the age of fourteen have not yet their menses generally die of consumption."

Dr. Holder's most accurate observations were made at an Agency school which was under his personal supervision. Concerning ten girls in it he was able to fix positively the ages at which the menses first appeared. These girls were received into the school when quite young, and the record of their ages made at the time is almost certainly correct. Three are half-breeds, seven full-blood Crow Indians. They menstruated as follows: One at 14½ years, one at 14 years, two at 13 years, three at 12 years, two at 11 years, one at 10⅔ years. The two at 13 and one at 12 are not yet quite regular. The one at 10⅔ has menstruated four times at proper intervals.

From so few cases it is of course impossible to make reliable deductions. The average for these ten girls is 12.91 years, while, according to the only American statistics (Emmet's), in the white race the average is 14.23 years. This early average

agrees with Dr. Holder's opinion, drawn from other sources and expressed above. It is also in accord with the opinion of such physicians in charge of Indians as have given him their views.

The duration of menstruation in the case of the above school girls was usually two days, rarely exceeding three. They have been remarkably free from pain or other unpleasant symptoms on the establishment of the function or at its recurrences.

Hot Water in the Treatment of Acne.

Dr. Frederick J. Leviseur, Dermatologist to St. Bartholomew's and Randall's Island Hospitals, New York, says in the *Medical Record*, September 13, 1890, hot water applied twice or three times a day for about five minutes is one of the most reliable local remedies which we possess for the treatment of acne of the face. To derive the full benefit from the effects of this simple remedy it is necessary that the physician, and through him the patient, should be thoroughly familiar with the proper method of using it. The water should be very hot, so hot, in fact, that it can hardly be borne by the patient. Care should, of course, be taken not to scald the face, but if the water is warm only, instead of really hot, more harm than good will be produced. The face should not be washed, rubbed or bathed with the hot water, as is so frequently done, but a small portion of the diseased area of the face should be soaked with it for a very short time only. The heat of the water, which is brought in contact with the skin, is deeply dissipated for a moment and causes an intense but transitory local hyperemia. This is exactly what we want to produce. If the hot water is allowed to act on the skin for too long a time, say more than a minute, or if the application is renewed at too short intervals, an acute inflammatory condition is added to the disease already existing. It is sufficient to go over the affected parts twice in one sitting and the entire operation need not take more than three to five minutes. A handkerchief or a piece of soft linen is commonly used to convey the hot water to the face. I use for this purpose a very simple glass holder which I have constructed. Since this little instrument, which I have named "Thermophor," has proved itself very useful and convenient I shall take the liberty of shortly describing it here.

The instrument consists of a handle and a head. The latter is nothing else but an ordinary short test-tube. About half of this tube is filled with cold water. A thick pad of absorbent cotton is tightly stuffed into the opening of the tube. The holder is then reversed and the water inside the tube allowed to soak the cotton. The latter is thus kept in place by dint of the weight and adhesion of the water. During these few preparatory steps water has been brought to the boiling-point in a small vessel on a stove or over a gas or alcohol lamp. The holder with the cotton is dipped into the hot water, left in it for a few minutes, and then carefully carried to the affected portion of the face.

The advantages of the "thermophor" are manifold. It saves the patient's hands from coming in contact with the hot water, it renders possible the use of water of very high temperature and makes it easy to confine the action of the heat to a limited portion of the diseased area. Besides it is clean, handy and cheap.

Not only plain, but also medicated hot water may be used in the manner as described above. Hot solutions of boric acid, bicarbonate of soda, salicylic acid, resorcin, etc., are all very serviceable. I have had excellent results from the use of the so-called "lotio alba" to which resorcin is added according to the following formula.

℞ Zinci sulphatis.
Potassii sulphitis . . . . . āā ℥i
Aquæ rosæ . . . . . f℥iv
Dissolve each of the ingredients in half the water, mix and add

Resorcini . . . . . ʒj
Sig. Lotion. Shake well.

This lotion is to be used hot at night, and cold in the morning.

Treatment of Cholera.

The chief medical officer of the Spanish army has published in the *Revista de Sanidad Militar* an article on cholera, in which he indicates the treatment that is, in his opinion, most satisfactory. When cholera is epidemic all cases of diarrhœa ought to be attended to, and treated by means of large doses of subnitrate of bismuth. He would also give thirty grains or more of subacetate of lead in four ounces of distilled or boiled water as an enema after each loose evacuation. In cholera no food should be given, but plenty

of acidulated water (without sugar) and ice. Enemas of seltzer water and champagne are useful. Soup, milk, jelly, and toast-water are worse than useless as long as the kidneys do not act, as they only serve as culture liquids for the pathogenic microbe in the intestines. Bismuth is useful in helping the feces to form more or less solid masses together with the septic products of the small intestine, and so retarding absorption in the large intestine. If the stage of asphyxia or general infection comes on he advises recourse, if possible, to oxygen inhalation. Failing these, or as additional methods of medication, rectal etherization and a dose of antipyrin, administered either hypodermically or per rectum, may be tried. Other means, such as rubbing, hot-water bottles, hypodermic injections of ether, alcohol, caffeine—or morphia when there is vomiting—though useful, must be considered entirely subordinate to those first mentioned, of which the writer regards the inhalation of oxygen as the most valuable. In order to treat the kidney affection, which is so frequently the cause of death, warm baths and poultices must be used, and when cerebral symptoms develop ice should be applied to the head, and leeches to the mastoid processes.—*Lancet*, September 13, 1890.

Mushroom Poisoning.

In an excellent article on mushrooms, in the *Boston Medical and Surgical Journal*, September 18, 1890, Dr. Edward J. Foster, says: From a study of the cases where the symptoms developed after eight or twelve hours, more than a very small amount of the fungus had been taken, the treatment by the usual methods of giving emetics, cathartics, astringents or stimulants, combined or alone, has, I find, been universally unsuccessful; but when the chief reliance has been placed upon atropia, the results have been most brilliant. It is true that I have the records of fatal cases where this drug had been given, but in such small doses ($\frac{1}{180}$ to $\frac{1}{60}$ grain), that I was not surprised at the result.

The symptoms indicate a poison whose action is liké that of morphia, and if it is to be combated successfully, the same treatment as used for an overdose of that drug must be given, namely, atropia in full doses, one-third of a grain at a time, for instance. One grain of atropia has been given in opium poisoning with success. I have treated at the Boston City Hospital, and reported, a case of poisoning by morphia, where I gave three-fourths of a grain of atropia—one-half grain at once, and one-quarter grain in ten minutes—and saved the patient. Wharton and Stillé state that while one-sixth grain of atropia has caused alarming symptoms, death has not been caused by a grain; therefore, I think that when we have present as powerful a poison as that found in the mushroom, we had best use the antidote in moderately large doses.

The treatment by atropia is based upon the perfect antagonism which exists between this drug and the poison of the Amanitas, which has been separated by Prof. Schmiedelberg, and named muscarin. The poison has been separated by others and variously named, according to the variety from which it was obtained. The merest trace of this alkaloid will arrest the pulsation of a frog's heart; and even after four hours Lauder Brunton states he has caused it to pulsate again by a minute quantity of atropia being brought in contact with the organ. This and other experiments showing the antagonism between these two poisons have been repeated by Prof. H. P. Bowditch at the Harvard Medical School. It acts as well upon mammals as upon frogs. My friend, Dr. F. H. Williams, Assistant Professor of Therapeutics, tells me that he has recently brought the subject of mushroom poisoning and its proper treatment to the attention of his students in the Harvard Medical School.

In the treatment of such cases, general principles should only guide us to remove any of the poison remaining in the alimentary canal, by emetics and purgatives, to support the failing powers by proper stimulation. But the treatment should not stop here; our reliance must be upon an antidote; the poison already absorbed must be counteracted, an antidote must be used; and that antidote, I repeat, is atropia.

Infection with Milk from Tuberculous Cows.

Dr. Karl Hirschberger has made, at the request of Dr. Bollinger, a series of experiments in the Pathological Institute at Munich on the inoculation of animals with milk from cows in various stages of tuberculosis. He attempts to answer the following questions:—1. Do tuberculous cows fre-

quently give infectious milk, or is their milk only exceptionally infectious? 2. In which forms of tuberculosis is the milk infectious —in localized or only in general tuberculosis? He made twenty experiments, and calls attention to the fact that inoculation alone can give decisive results, because it is very difficult to observe tubercle bacilli microscopically in the milk, and impossible to discover their spores. On the strength of his experiments he states that the danger of infection from the milk of tuberculous cows does not only exist, but is very great, being found in 55 per cent. of all cases examined. The more the tuberculosis has spread the greater is the danger; but even in mild cases of localized tuberculosis the milk is, he considers, more or less infectious.—*Lancet*, August 30, 1890.

NEWS.

—Dr. Frederick A. Packard has removed to 131 South Fifteenth street, Philadelphia.

—A report of a burial alive comes from Pittsburgh, Pa., under date of October 22.

—Prof. Theophilus delivered the annual address at Lafayette College, on October 22, "Founder's Day."

—Dr. J. B. Mattison, of Brooklyn, delivered, by invitation of the Directors, an address on the Renal Status of Opium Habitués, before the Philadelphia County Medical Society, on October 22.

—It is reported that a nurse at Bellevue Hospital, on October 21, killed a patient by striking him in the face with his fist. The patient was suffering with delirium tremens, and had spit in the nurse's face.

—King William, of Holland, has recovered his physical strength almost entirely and looks now as though he might live years, but his mental faculties are shattered. He has, it is said, forgotten his name, and is not able either to read or write.

—The friends of Dr. Francis L. Haynes, formerly of Philadelphia and now of Los Angeles, California, have been much annoyed by newspaper reports which contained insinuations in regard to his relations to a companion who was killed, it is said, by Indians in Arizona.

—On October 21, Dr. John B. Deaver at St. Agnes' Hospital, Philadelphia, successfully amputated the left hip of a young woman by what is known as the "Wyeth bloodless operation." Though the operation required almost three-quarters of an hour, it is said that only about an ounce and a half of blood was lost.

—The County Dental Society of Philadelphia has adopted a protest against dentists being classified by the Census Bureau with manufacturers, and instructed its members to decline "to attempt the impossibility of making any returns" upon blanks under such classification.

—The American Humane Society offers two prizes, each of $250, for the best essays on the question whether vivisection should be permitted in the interests of humanity, and, if so, with what restrictions. Essays should be sent to George T. Angell, No. 19 Milk street, Boston, before January.

—The opening exercises of the new Keokuk Medical College were held September 25. Many of the members of the faculty were connected with the College of Physicians and Surgeons of Keokuk until the close of last term, when they withdrew and founded the Keokuk Medical College.

—The Superintendent of Police of Philadelphia has ordered that hereafter when an insane person has been brought to the station and the police surgeon was notified of the fact, and he sends word that he will be there at a certain hour, the police shall find out, if possible, whether the patient has any relatives or friends, and, if so, shall send for them and have them present at the station house to meet the Police Surgeon when he arrives.

—It is reported that the United States Marine Hospital Service will recommend the plan of having a systematic examination of all persons intending to immigrate to this country. This examination would be made by physicians attached to the United States consulates. It is to be hoped that some such measure may be attempted. It is cheaper to keep out the sick, criminal and defective classes, including anarchists, than to support them here or send them back.

—Dr. Clarence Thwing, of Brooklyn, has accepted an invitation to establish one or more missionary hospitals in Alaska, beginning at Sitka. He was graduated about three years ago, since which time he has been engaged in special courses that will fit him for his new and responsible berth. His father, also a physician and a clergyman as well, has become known through his advocacy of the establishment at Hong Kong of an asylum for the insane, which, if he succeeds, will be the first of its kind on Chinese soil.

CH. MARCHAND'S

Peroxide of Hydrogen,

MEDICINAL (ABSOLUTELY HARMLESS)

H_2O_2

is rapidly growing in favor with the medical profession. It is the most powerful antiseptic known, almost tasteless, and odorless. Can be taken internally or applied externally with perfect safety. Its curative properties are positive, and its strength and purity can always be relied upon. This remedy is not a nostrum.

Experiments of Prof. Pasteur, Dr. Koch, and many other scientific authorities, prove beyond doubt that Germs, Bacteria, or Microbes cause and develop: **NOSE, THROAT, AND LUNG DISEASES—Diphtheria, Croup, Sore Throat, Catarrh of the Nose, Hay Fever, Bronchitis, Laryngitis, Pharyngitis, Whooping Cough, Consumption and other Chronic Affections, specific or not.**

GERMS, BACTERIA, OR MICROBES are instantaneously annihilated when brought into contact with **Ch. Marchand's Peroxide of Hydrogen.** This wonderful bactericide acts both chemically and mechanically upon all excretions and secretions, so as to thoroughly change their character and reactions instantly. By destroying the microbian element this remedy removes the cause of the disease.

CAUTION.—I would earnestly impress upon the profession the very great importance of prescribing only my Peroxide of Hydrogen (Medicinal), from which all hurtful chemicals have been eliminated.

By specifying in your prescriptions "Ch. Marchand's Peroxide of Hydrogen (Medicinal)," which is sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing my label and signature, you will never be imposed upon.

Prepared only by

Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

A book containing full explanations concerning the therapeutical applications of Ch. Marchand's Peroxide of Hydrogen (Medicinal), with opinions of the profession, will be mailed to physicians free of charge on application.

¼ lb. bottle, retail, 35 cents; ½ lb. bottle, retail, 50 cents; 1 lb. bottle, retail, 75 cents.

SOLD BY LEADING DRUGGISTS.

Laboratory, 10 West Fourth Street, New York.

BURN BRAE

A PRIVATE HOSPITAL

--FOR--

MENTAL and NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

EXTENSIVE AND BEAUTIFUL GROUNDS, affording perfect privacy and pleasing variety. House and surroundings unusually attractive and cheerful. Heat, light and ventilation perfect.

A PLEASANT, SAFE AND HEALTHFUL HOME,

With constant professional supervision. Music, games, open-air amusements, boating, etc., are provided for patients.

THE OLDEST INSTITUTION OF THE KIND IN THE UNITED STATES.

Both sexes received. A limited number of opium habitues admitted. Pleasant companions for female patients.

LOCATED A FEW MILES WEST OF PHILADELPHIA,

At Primos Station, on the Philadelphia and Media Railroad, from Broad Street Station, Philadelphia, Pa.

Clinical Lecture.

AORTIC REGURGITATION. — FUNCTIONAL HEART DISEASE.[1]

BY J. M. ANDERS, M. D.,

PROFESSOR OF CLINICAL MEDICINE, MEDICO-CHIRURGICAL COLLEGE, PHILADELPHIA, PHYSICIAN TO THE EPISCOPAL AND PHILADELPHIA HOSPITALS.

The first patient, J. T., 72 years old, with a negative family and previous personal history, was before you last week, when I diagnosticated for you an aortic systolic murmur and discussed its significance. In cases of aortic regurgitation we hear a murmur most distinctly at the second costal cartilage, on the right side. On ausculting this patient we find a double murmur, or a murmur accompanying both the first and second sounds of the heart. These murmurs do not replace the second sound. Cases frequently occur in which a murmur is heard replacing the second sound. In all cases of diastolic murmurs notice carefully what is their area of diffusion. Some diastolic murmurs may be transmitted to the xyphoid cartilage and to the apex as well. In other cases, diastolic murmurs will be heard for only a few inches down the sternum. When the posterior segments of the aortic valve are affected, the murmur heard will be transmitted to the apex of the heart. When only the anterior segment of this valve is involved the murmur is heard only at the sternum. Cases of aortic valvular disease in which the anterior segment of the valve is the seat of trouble are of graver import, owing to the position of the coronary arteries. In the patient now before you we hear a murmur which is transmitted to the apex and into the axilla. In some of these cases you may hear the murmur in the back and in the arterial branches, even into the radial arteries.

We rarely find a case of aortic regurgitation without constriction being also present, though the reverse is more frequently met with. When two murmurs are associated, we may get one continuous sound between systole and complete diastole. In this patient there exists a distinct pause between the two murmurs.

Let us see what conditions may be mistaken for those present in this case of aortic regurgitation. In our efforts at diagnosis we may disregard all systolic murmurs. The pre-systolic murmur in cases of mitral stenosis might be mistaken for this form of valvular disease. The pre-systolic murmur of mitral obstruction, however, occurs, as its name implies, *before* the first sound; it is best heard at the apex, and the murmur is not transmitted to the axilla, to the back or into the carotids. It is a long, rough, blubbering or churning sound. The murmur of tri-cuspid insufficiency is a soft, short, low-toned, blowing murmur, and is not heard above the third rib. An aneurism at the sinuses of Valsalva may give rise to a murmur resembling somewhat that of aortic regurgitation. In aneurism, in the first place, we will get a history of pain and cough, and later we may find characteristic bulging of the intercostal spaces with dulness on percussion over the same area. The aneurismal bruit is confined to the seat of the trouble, is frequently double, and we will fail to find with it any enlargement of the left ventricle.

The subjective symptoms of aortic regurgitation at first may not be marked, if the heart's action is regular. The patient may suffer with pain over the site of the left ventricle, this symptom being more marked in this form of valvular disease than in any other form. A white line can often be traced on the skin, following the course of the pain and extending to the shoulder. The pain may radiate to the right as well as to the left side. In this patient we may get attacks of angina pectoris. Exertion aggravates the pain and produces dyspnœa and

[1] Delivered in the Medico-Chirurgical College.

palpitation. The patient becomes fretful and dislikes all exertion. As the case progresses these symptoms become more marked. When, through the existence of this lesion, the heart fails to do the work required of it, the left ventricle, from over-distention, first becomes dilated and then often, as here, greatly hypertrophied, and, in consequence, greater amounts of blood are forced into the arterial system; and thus endarteritis is set up in the vessels throughout the body. From this cause we also find produced a form of rheumatism, as in the knees and other large joints. This case illustrates the form of rheumatism *following* and being *caused* by heart lesions, as shown, pain and tenderness around the knee-joints having been only quite recently developed. This rheumatism, if such it may be termed, is due to endarteritis in the vessels surrounding the joints.

Cerebral anemia will soon make its appearance, and will be shown by attacks of dizziness, syncope, etc. The symptoms of cerebral anemia precede those of venous engorgement.

Next, owing to the dilated condition of the left ventricle and nutritive changes in its muscular tissue, we have a loss of contractile power in the ventricle, and through this lack of propulsive force in the circulatory system, venous stasis results and œdema makes its appearance—first in the lower extremities.

In aortic regurgitation, the pulse is regular and full, but it seems to collapse under the examining finger, giving a quick pulse, but without increase in the number of beats in the minute. This peculiarity may be best observed by holding the patient's arm up as I now do, when feeling the pulse. This is known as "Corrigan's pulse" or the "water-hammer" pulse, the latter name because of its vibratory character.

The treatment of this condition is indirect in the earlier stages. In these cases no medicines are given for their direct cardiac effect, unless we find evidences of failing cardiac power. Use dietetic and regiminal methods, such as frictions of the skin. Avoid all violent exercise. An occasional warm bath may be used. We will use, in this case, a preparation of iron, to aid in preserving the cardiac muscle, giving ten minims of the tincture of the chloride three times daily. If there is a decided weakening of the heart muscle, as shown by venous engorgements, we may use tincture of digitalis in five-minim doses, four times a day, and gradually increase the dose to ten minims. If the patient complains of precordial pain, it means that the remedy is not exerting a good effect. When using digitalis we need have no fear of bad effects from the use of the remedy as long as we find an increased flow of urine.

Functional Heart Disease.

The patient I now show you is a young man, 20 years old, whose family history is generally good; though one of his parents died of phthisis. The patient's health was good up to four weeks ago. His habits are good, excepting that he is addicted to the excessive use of tobacco. He has used tobacco, though at first moderately, since he was twelve years old. Four weeks ago he began to suffer with dyspepsia and cardiac palpitation. The day preceding the beginning of his trouble he ate largely of apples and drank a great amount of water. This, then, gives us a history of dyspepsia ushered in by an attack of acute indigestion. The heart-trouble is worse in the morning on first rising, amounting to an attack of violent palpitation lasting from two to three hours, and it is accompanied by extreme apprehension.

Physical examination.—Inspection shows the apex beat at its normal location. Palpation shows the area of heart impulse to be a little increased, due to violence of cardiac action. Percussion fails to show any increase in the size of the heart. Auscultation gives us the following points: the heart's action is sharp and quick, the first sound of the heart lacks the sound of muscular contraction but possesses a stronger valvular element.

This is a case of functional disease of the heart. In diagnosticating functional troubles, besides taking into account the subjective symptoms, we must make a careful physical exploration, with a view to excluding organic affections. In this case two leading causes have been at work in producing the trouble: indigestion and the excessive use of tobacco. Here there is also a nervous predisposition; and this is probably true of all instances of this class of ailments. Other causes of functional disturbances we find in anemia, excessive use of tea and coffee, severe and prolonged mental application, excessive venereal excitement and muscular exhaustion.

The prognosis is good; and such patients must be assured at each successive visit that

their disease is not a fatal one under any circumstances. This piece of positive information will be of inestimable service.

In the treatment we must try to give these patients *immediate* relief from the paroxysms of palpitation which are the cause of the painful mental apprehensions. Try to appreciate the individual's condition and treat him accordingly. You will meet with two leading classes of cases of the affection under consideration. To one class we must give diffusible stimulants, such as ammonia, whiskey or Hoffmann's anodyne; since we find irregularity in the heart's action, and at times the pulse intermits. If the heart is working regularly, but too rapidly, we may use anti-spasmodics, arterial and nervous sedatives, such as bromide of ammonium; or, if this remedy does not act promptly, tincture of aconite root, in doses of two or three minims, three times a day, to be persevered in for two or three weeks. It is in this instance highly important to treat the digestive symptoms. We will use one drachm of essence of pepsin, with ten minims of the fluid extract of cascara and ten grains of bromide of ammonium three times a day.

The cascara is added because the patient has been for a long time troubled with constipation. Tobacco shall be discontinued. Indeed it may be stated as a positive rule, that our efforts to cure these functional diseases will be successful just in so far as we are able to control and remove their known causes. In conclusion, let me urge you to bear in mind the necessity for relieving the mental apprehensions of the patient as frequently as possible by your positive assurances that he has a curable complaint. This patient admits that we have even prevented attacks of palpitation in this manner.

—Biblical units have the following equivalents: A shekel of gold was $8. A firkin was seven pints. A talent of gold was $13,809. A talent of silver was $538.30. Ezekiel's reed was nearly 11 feet. A cubit was nearly 22 inches. A bin was 1 gallon and 2 pints. A mite was less than a quarter of a glass. A shekel of silver was about 50 cents. A piece of silver, or a penny, was 12 cents. A Sabbath day's journey was about an English mile. An ephah, or bath, contained 7 gallons and 5 pints. A day's journey was about 23.5 miles. A hand's breadth was equal to 3⅝ inches. A finger's breath was equal to 1 inch. A farthing was 7 cents.

COMMUNICATIONS.

NERVOUS AND MUSCULAR ELEMENTS IN THE CAUSATION OF IDIOPATHIC LATERAL CURVATURE.[1]

BY BENJAMIN LEE, A. M., PH. D.,
PHILADELPHIA.

"*Propter ovarium est mulier:*" woman, exists for the ovary. The ovary is the dominant in the scale of her physical harmonies. Let that organ lose its normal tone, and discord soon manifests itself in some portion of her nervous system. Up to a certain age it remains dormant, and, given similar conditions of life, training and regime, there is little to mark the difference between the boy and the girl. But when once this gland has taken on its functional activity, all this is changed, and the budding woman becomes liable to numerous distresses and disorders which her more fortunate brother never or rarely suffered from. When both were infants in arms, their backs—that is to say, their spinal columns—were nearly straight, deviating from a right line neither forwards nor backwards, neither to the right nor the left. As they begin to bear their weight upon their feet, to balance themselves and to walk, gradually these straight spines began to curve forwards in the lower segment, backwards in the middle segment, and again forwards in the superior segment. The first of these curves took place in the lower or lumbar region as the results of increased tonicity in two important muscles known as the psoas magnus and the iliacus intemus. The other curves were compensatory in order to preserve the equilibrium of the body and afford all the organs room for free play and complete discharge of function.

But now for the possessor of the ovary comes the monthly molimen which for the next thirty or forty years of her life is to regulate all her movements. This imperious organ becomes engorged with blood, takes on an intense excitement, sets all its nerves to vibrating, and arouses the sacral plexus into a state of sympathetic energy. In many cases the sacral plexus in its turn communicates the unwonted stimulus to the pelvic spinal muscles of which mention has

[1] Read before the American Orthopedic Association, at its meeting held in Philadelphia, September 17, 1890.

just been made. These muscles contract under the stimulus, and the result is a backache such as the sufferer never felt before. The means to which she naturally resorts for relief is to lie down and place her hand or some other firm body under the small of the back. This supports the arch formed by the contraction of the muscles, allows them to relax and diminishes the suffering. When the flow of blood from that obedient slave of the ovaries, the uterus, has relieved their congestion, their excitement diminishes, this intelligence is communicated to the sacral plexus, which in turn telegraphs to the muscles, and they soon subside into their normal condition, only to be again stimulated to undue contraction when the moon shall have completed another revolution around the earth. In many women this pain is slight, in some it is entirely absent; but it is safe to say that it is the most common form of suffering attendant upon menstruation. And even when there is no consciousness of pain, it does not follow that a certain degree of muscular contraction has not taken place. We have these muscles then subjected at very frequent intervals to an influence which unduly excites their contractility. Is it to be wondered at that this intermittent abnormal contractility should sometimes lead to a permanently irritable condition of the muscular tissue? So long as these symmetrical muscles act with equal energy on both sides of the flexible spinal column, its equilibrium will not be disturbed, so far as lateral deviation is concerned. But if, for any reason, those of one side act more vigorously or more persistently than their fellows, the result must be a gradual inclination of the spinal column towards the side of preponderating contraction. The same effect will of course be produced if those of one side suffer a loss of tone. Now bear in mind that these muscles have an entirely different relation to the motility of the spinal column from that possessed by the muscles of the upper part of the trunk, in that their attachments are to a fixed point of support which is in contact with the earth, while those of the former, such as the rhomboideus and trapezius, are two eutirely movable points. The direction of action is here precisely reversed. The spine itself is the fixed point, so far as the superior muscles of the trunk are concerned. When they contract, they do not draw the spine towards their opposite extremities, but draw their opposite extremities, with the limbs to which they are attached, towards the spine. Only under one condition can they disturb the spinal equilibrium, namely, when the hand grasps an object which is firmly attached to the earth. Then they act with the same advantage that the pelvic spinal muscles possess in that respect.

There is, however, another mechanical consideration to be borne in mind. Acting from the pelvis as a fixed point or centre, the spinal column forms the radius of a circle. A very slight degree of deviation from the perpendicular near its pelvic extremity therefore means a very considerable deviation at its capital extremity. Hence as the maintenance of equilibrium is the first necessity, a very small lumbar curve will necessitate a large dorsal compensating curve. It is not strange that the comparatively trifling lumbar curve often goes unnoticed and that the large dorsal curve is the first to attract the attention of the mother or the dressmaker. In fact in the large majority of cases the mother does not detect the former, even when it has become aggravated, until the surgeon points it out to her.

I have said that under ordinary circumstances it is not conceivable that the use of the muscles which move the upper extremity should draw the spine towards the extremity. The extremity must of necessity be drawn towards the spine. We cannot attribute the dorsal curve to direct traction by those muscles, however excessively that may be developed. But there is an indirect action upon the equilibrium which must not be overlooked, and which will aid in the solution of our problem. Every time that we make a vigorous movement of the right arm, we instinctively throw our weight on to the left leg, with the double object of preserving the equilibrium and of obtaining a stronger *point d'appui* for the effort. The result of this constant use of the left leg as the antagonist of the right arm, is to make it the stronger of the two. We even find in a large proportion of individuals the left foot the larger. In this general disproportionate development of the muscles of the left leg, of course the pelvic spinal muscles share. If they are in a perfectly healthy condition however, their increased development does not induce abnormal contraction, and there is no disturbance of equilibrium. But if they are in a state of morbid irritability it is not difficult to understand that the excessive strain upon them may lead to

an abnormal contractility approaching tonic spasm.

I do not forget that when this subject was under discussion at the Washington meeting, Dr. Ketch made the statement that, in two hundred and twenty-nine cases of lateral curvature which he had analyzed, he had found forty occurring in boys. This fact, taken as it stands, is enough to point to some sexual influence as a strongly-predisposing cause, showing that only a little over seventeen per cent. of the cases were found in boys. But I strongly suspect that all forms of lateral deviation of the spine were included in this analysis, and that such as are dependent on rachitic degeneration, pulmonary or pleuritic inflammation, inequality in the length of the limbs, and accidents of various kinds, had been eliminated, the disproportion would have been greatly increased.

It is quite possible to conceive that sexual irritation arising from preputial malformation may produce in the male, during the period of awakening sexual energy, precisely the same disturbance of the pelvic ganglia that ovulation does in the female. We know how frequently both paralysis and spastic contractions can be traced to this cause.

Viewing the general question of the precedence of the curves from a clinical standpoint, I would request the members to note particularly in their cases, in the very earliest stages, whether with very slight dorsal curvature and rotation, they do not often observe quite marked distortion of both kinds in the lumbar region. Such has been my own experience, and it was that which led me to the line of thought which I have now hastily sketched.

HYPODERMIC TREATMENT OF ASTHMA.

BY WILLIAM S. HIGBEE, M. D.,
PHILADELPHIA.

Miss E. M., 25 years old, born in Ireland, dressmaker, contracted a severe cold at the age of thirteen, by bathing her feet in a cold stream of water while menstruating for the first time. She was confined to bed for nearly six months suffering with cough, shortness of breath and amenorrhœa. Her menses gradually reappeared, but remained scant and painful. Her asthma occurred frequently and continued until she was eighteen years old, when, under the advice of her physician, she emigrated to America, where she seemed to improve for about two years. After this time, however, her health began to decline gradually, and the asthma returned with greater severity. She returned to Ireland, stayed there one month without relief and again came to this country, after which I saw her for the first time and treated her with indifferent success. Last January she had a severe attack of influenza, and, after convalescing from this, her asthma was decidedly worse. On June 9, 1890, she was bedfast, with her general health much impaired, and with marked loss of weight. Her appetite and digestion were poor, her pulse rapid and weak. There was no albumin in her urine. Loud sibilant râles were heard over the whole chest. Her family history shows that her father, sister and brother and her uncle and grandfather on her father's side were sufferers with asthma.

At this time I gave her morphia sulphate, $\frac{1}{8}$ of a grain, and atropia sulphate $\frac{1}{120}$ of a grain, and ten grains of antipyrin, with ten drops of tincture of nux vomica every four hours, with favorable results; but after giving her this treatment for four days I decided to place her on hypodermic injections of strychnine and atropine, as recommended by Dr. Thomas J. Mays, in the MEDICAL AND SURGICAL REPORTER, April 12, 1890. All other treatment was discontinued, and she received $\frac{1}{50}$ of a grain of strychnine, and $\frac{1}{200}$ of a grain of atropine every other day for two weeks. On account of the profound dryness produced by the atropine, even in small doses, it was then omitted, and the strychnine in the same doses was continued alone until October 1, since which time she has been taking $\frac{1}{30}$ of a grain of strychnine and two grains of Vallette's mass three times a day.

She has been free from asthma for three months, and has gradually but steadily improved. She weighs more than she ever did, and loses no sleep or rest at night; she has a good appetite, and is able again to attend to her business, which she had been forced to relinquish. By October 24, she had gained twenty-three pounds in weight.

—Japan is about to enter the field as a producer of indigo. The soil and climate of parts of the island are stated to be favorable to the cultivation of the shrub, and the Japanese Government favors its cultivation.

TONSILLITIS.[1]

BY FRED. T. KIDDER,
WOODSTOCK, VT.

The tonsils are the two glands which occupy the excavation on each side of the base of the tongue, limited by the pillars of the fauces. They are oval-shaped bodies, and project into the isthmus of the fauces. They may vary greatly in size and still present no pathological changes. Their object seems to be to serve a double purpose. First, the numerous acinous glands, which make up the tonsil, secrete a clear viscid liquid which is destined to lubricate the food and to assist it in its passage through the pillars of the fauces and œsophagus to the stomach. The lacunæ always contain fluid which is poured forth by the contraction of the muscles of deglutition. Second, like the other ductless glands which they resemble, they modify some of the constituents of the blood, aid in the formation of the white corpuscles and contribute to the elaboration of the lymph.

Tonsillitis is an acute inflammation of the tonsil or tonsils which may be superficial or parenchymatous, and may terminate in resolution, suppuration, or chronic enlargement. I shall not speak of those conditions of the tonsil which are symptomatic of general disease, or erysipelas, the eruptive fevers, and traumatism, but simply of those varieties which are classed under the general head of acute tonsillitis, viz. : the erythematous, parenchymatous and follicular or lacunar. The disease is most common in early adult life and is not confined to either sex. Pale, lymphatic children are most apt to have inflammation of the tonsils and one or more attacks make the patient more liable to a recurrence of the inflammation. Cold and dampness, as well as an overheated and vitiated atmosphere together with septic influences, are among the most common of the exciting causes. The symptoms vary according to the form of the disease which is present, from the simple erythematous to the more alarming and painful follicular variety. The first indications of acute superficial or erythematous tonsillitis are a slight chill, with perhaps nausea and vomiting, and a slight elevation of temperature. After a few hours, the patient complains of a dryness about the throat, followed by more or less pain and difficulty of deglutition. There is generally some cough and expectoration of a stringy mucus, which collects in the throat. The tongue is coated with a white fur, the bowels are constipated, and the breath foul. The breathing is rapid, and the temperature may rise to 102° or 103°. At this time the throat and tonsils will be found red and swollen, and at times may be covered with a grayish exudation. These cases last but a few days, and end in resolution ; although after repeated attacks hypertrophy of the tonsils may result.

Parenchymatous tonsillitis, or inflammation of the subtance of the tonsil, is in its initiatory stages similar to the erythematous variety, and may appear to be nothing but that at first. After a few days, however, the symptoms increase instead of decreasing in severity, and one of the tonsils begins to increase in size, and becomes much more painful ; the swelling extends to the adjacent parts, so that swallowing is almost impossible; and the voice becomes nasal in character or is reduced to a whisper. The inflammation may involve the Eustachian tube, producing pain in the ear, and occasionally acute suppuration of the middle ear. If the disease goes on to suppuration, all the symptoms increase until the abscess either is opened or opens itself. In early life the formation of an abscess is uncommon, and the disease generally ends in resolution.

In follicular, or as it is more properly called, lacunar tonsillitis, the inflammatory process is located in the crypts of the tonsil; a soft cheesy deposit being poured out from the follicles, and forming a number of small patches corresponding with the number of crypts affected. The clinical importance of this variety is considerable ; and it is of this that I wish to speak more in detail.

The symptoms from the beginning are much more severe, and it generally runs a more protracted course. Beginning with a chill and all the active symptoms of an acute inflammation, the temperature rapidly rises to 103° or 104°, with a pulse to correspond. The throat has first a feeling of dryness and then grows rapidly worse ; the tonsils become inflamed and greatly swollen, and in a few hours are covered with a membrane-like deposit, formed from the secretion of the follicles of the organ. After a variable period of from ten to fourteen days, the symptoms begin to subside, leaving, however, a notable degree of general depression

[1] Read before the Vermont Medical Society.

of the system for many days, as great as many times follows diphtheria; together with paralysis of the soft palate and pharynx. The main source of anxiety in the diagnosis, in the early stages of the disease, is the danger of confounding it with diphtheria, which from the severity and character of the symptoms it strongly resembles. I have no doubt many cases of so-called diphtheria are nothing more or less than lacunar tonsillitis.

Usually the disease can be distinguished from diphtheria by the character of the deposit on the tonsil, which in tonsillitis is easily removable with a brush, and no ulceration is found beneath it; while in diphtheria the deposit in the throat is more in the form of a membrane of a leathery appearance, is more tenacious, and on removal leaves a raw and inflamed spot behind it. But in those unusually severe cases where there is a doubt as to the character of the deposit, if on removal it returns in the course of twelve hours with all its original characteristics, the disease is undoubtedly true diphtheria. In tonsilitis also the membrane is confined to the surface of the tonsil, while in diphtheria it is rare not to see patches on other parts of the throat at the same time. One other, and perhaps the chief, reason for confounding the two diseases is the evident lack of belief in the contagiousness of lacunar tonsillitis.

In the summer of 1886 my attention was called to the fact that it might be contagious, since which time, from the few cases that have come under my observation, my belief in the septic origin of many cases of it has been strengthened. In August, 1886, I was called to see a man suffering with a well-marked attack of lacunar tonsillitis, which ran its usual course and was not very severe. He lived on a farm, with good drainage about the home and good sanitary surroundings. At this time I had never had the slightest trouble with my throat and was in a perfectly healthy condition so far as I know. In nine days I began to feel that something was the matter with me, and especially with my throat. The following day I had a distinct chill, followed by a rapid rise in temperature and fast increasing soreness of the throat, which developed into follicular tonsillitis, so that I was confined to the house about ten days.

In January, 1887, I was called to see a child who was a member of a family consisting of seven persons. I found the child sick with tonsillitis, and the next day a second child came down with the same disease. Upon inquiry I found that an aunt who lived in the family had been sick about ten days before, with what she termed a sore throat, which the mother said had just the same appearance as the throats of the children. In about ten days from the time these two were taken sick, three more came down with the same disease, making six out of the family of seven that suffered from tonsillitis. This was a well-to-do family, and the drainage and sanitary condition of the house were as good as they could be in a country village. I did not see another case of the disease until the following winter, when I again contracted it myself, coming down in about the same time and in the same manner as before.

Last winter I had three cases, two of the patients being mother and son, and the third a young lady who called to see them while they were sick. She was taken sick in seven or eight days from the time she made the call.

Dr. Beverly Robinson says in regard to tonsillitis: "While it is true that many cases of follicular tonsillitis cannot be definitely and distinctly traced to a septic cause, I am more and more convinced that the influence which underlies such evident derangement of the *prima via*, accompanied by chills and anorexia, is due to specific germs or entities present in the body. If we do not find them, I prefer to think that our means of research are not capable of demonstrating them. . . . The resemblance between the symptoms of this disease and those of other diseases, whose pathogenic micro-organism is known, leads me to conclude from analogy that a more or less similar germ is present here also."

I am well aware that tonsillitis in any form has not been generally classed among the contagious diseases; and I have been unable to find any record of cases kept for the purpose of establishing or denying the fact of its being caused by a specific germ, or any suggestion that such might be the case, except in Keating's *Cyclopedia of Diseases of Children*, in an article by Dr. Robinson, part of which I have quoted. Of course we cannot reason from the particular to the general, and the few cases that I have been able to collect do not by any means establish the fact, nor do they go far to prove the contagiousness of tonsillitis. It is true there might have been no contagion about these few cases, and they may have

happened to appear in such regular order from being produced in one by the same cause that produced it in the other; nevertheless in these days when a germ is found for so many diseases that were formerly classed as non-contagious, why is it not possible and even probable that tonsillitis may have a microbe of its own which is capable of being transmitted from one person to another under favorable conditions?

In regard to the treatment I will say a few words. Guaiac is the best remedy, recommended to abort an attack. I have used it with good results in erythematous tonsillitis, but have never been able to abort an attack of follicular tonsillitis by its use. In any case it must be given in the earliest stages of the disease. Tincture of iron is probably used more than any other one remedy. I give it with glycerine—two drachms of iron in two ounces of glycerine, giving a teaspoonful every two hours. I have thought the effect was better in combination with glycerine than by any other mode of administering it. I am not a believer in gargles of any kind; for the reason that the irritation from using the muscles of the throat, as is necessary in gargling, is a disadvantage which more than counterbalances the advantage gained from the remedies. Sprays and inhalations of steam give some relief and are of decided benefit. Whether they tend to cut short the attack or not, they certainly are comforting to the patient. In a severe case sedatives are required, to give needed rest, and they should be administered. Particular symptoms should be treated as each case requires; and one has the satisfaction of feeling that with proper care the patient can be made fairly comfortable and recovery is almost sure to follow.

NECROSIS OF PART OF THE ALVEOLAR PROCESS.

BY C. H. M. NEALL, M. D., D. D. S.,
PHILADELPHIA.

A gentleman called at my office on June 11, 1890, suffering with aching in the three teeth on the left side of the lower jaw—the central, lateral and cuspidate teeth—all of which were badly decayed. In connection with this there was an abscess situated anterior to the teeth and pus was exuding therefrom. I extracted the decayed teeth, and also opened the abscess freely and scraped the cavity, treating it with carbolic acid twenty drops to the ounce, and instructed the patient to syringe out the cavity with the same solution after each meal; so that no food might collect and set up more inflammation. He returned to my office the next day, saying that he was unable to sleep, and his mouth was giving him a great deal of pain. I examined it, and found pus exuding from the cavity, and also a loosening to a certain extent of the first bicuspid. I carried out the same plan of treatment that I did at first. On the 16th of June he returned to my office, and upon examination I found pus also exuding from the cavity; and this time I syringed the cavity out with a 1:1,000 solution of corrosive sublimate. On the 24th he returned, and I cut down through the gums and detached a piece of necrosed bone, extending from the central to the cuspidate in length, and from the alveolar border to its attachment to the lower jaw in width. The hemorrhage was quite profuse, for a very short time; and the odor was very offensive. I syringed out the cavity with the 1:1,000 solution mentioned before, and plugged it with cotton when I removed the bone and directed the patient to remove the plug often during the day and to syringe out the cavity himself. On July 5, he returned to my office, everything doing nicely. The tooth that was loose had become firm, and the parts were closing up.

REPORTS OF CLINICS.

BUFFALO GENERAL HOSPITAL.

ORTHOPEDIC CLINIC.—DR. BARTOW.

Potts' Disease.

This girl, ten years old, had Potts' disease, with beginning kyphosis of the dorsal region. Dr. Bartow said that it is important to recognize this disease at an early stage, in order to institute immediate treatment and to prevent angular deformity. At times it is impossible to diagnosticate between Potts' disease at an early stage and scoliosis, both presenting rotary-lateral curvature; and in such cases it is better to treat by fixation, on the hypothesis that Potts' disease exists.

The child was suspended by the chin, occiput and axillæ, and a sleeveless undergarment was put on, a pad of gauze was

placed over the kyphosis and a thin dinner-pad was applied, and then the plaster jacket was put on, extending from the axillæ to the trochanters.

SURGICAL CLINIC.—DR. PHELPS.

Fistula in Ano.

The second case was one of fistula in ano, in which the fistula was divided on a director and the wound was packed with iodoform gauze.

Abdominal Abscess.

The next case was one in which Dr. Phelps had opened an immense abscess in the region of the cæcum two weeks before. It had been treated on the assumption that it was a perityphlitic abscess, but it had not done as well as he would have liked. The evening temperature on the day before the clinic was almost 102°. There was an immense amount of pus running from the cavity, and even by washing it out twice a day, it could not be kept clean. The pus looked very creamy, as if it might have come from diseased bone somewhere; but on examination the fascia over the psoas was found intact; so that theory had to be abandoned. A counter-opening was made posteriorly and a drainage-tube was drawn through.

Sacro-iliac Arthritis.

The next patient was a girl, seventeen years old, who came into the hospital four weeks previously to the clinic, complaining of severe pain about the hip, with a temperature of 103°, and it occurred to Dr. Phelps that there was hip-joint disease. Pressure on both trochanters as well as on the knees gave pain, and the crease in the upper part of the thigh was apparently less on one side. There was also pain on pressure over the joint in front. The girl was put to bed and extension applied and she had improved very much. She had no fever when shown in the clinic, and there was no pain from pressure on the knee. Dr. Phelps said that Dr. Bartow thought the trouble was in the sacro-iliac joint, and that he had a method of applying a plaster of Paris spica, thereby securing fixation without the weight and pulley, and while the patient was going out of doors.

At the request of Dr. Phelps Dr. Bartow addressed the class. He spoke as follows: "I have not seen this case before. Although the long-continued treatment would tend to relieve the spasm of the joint, it would seem that if there was inflammation of the capsule or tissues about the hip-joint, it would be impossible to draw up the knee as freely as I do now. Pressing the head of the femur inward against the acetabulum is not very painful, all the pain being referred to the sacro-iliac articulation. Pressure over the sacro-iliac joint causes pain as does indirect pressure brought to bear by expansion of the ilia. Pulling on the limb hurt her before, but it does not now. She has had no pain referred to the knee. For these reasons I think the lesion is in the sacro-iliac joint. The treatment is, first, to suspend the patient to get rid of voluntary malposition, leaving simply the reflex, spasmodic malposition. I then apply a spica, using only the weight of the limb as extension, a high shoe being placed on the other foot. The patient will be directed to go about on crutches. After four to six weeks, the bandage is removed, and I often find the deformity almost entirely gone."

The spica was then applied according to the method indicated. The plaster of Paris bandages began at the trochanter and they were continued up well above the pelvis and down to a point two inches below the knee. Three steel strips were included in the bandages on the outer side of the hip and thigh.

Special Correspondence.

LETTER FROM NEW YORK.

Revival of Activity.—The Academy and the Medical Societies.—Skin Grafting by New Methods.—New York and Her Neighbors.—The Death-rate and the Census.—Physicians and Good Government.

Life is again reviving in medical circles after the quiet of the summer. Many of our physicians spent the summer in Europe, the principal attraction being the International Medical Congress at Berlin. The attendance at the Academy of Medicine at its first meeting in the new building, West Forty-third street, October 2, was large. Dr. Loomis presided, and said the formal opening would take place November 20. The building has fifty feet frontage, and presents rather an imposing appearance. There seems to be room enough within to meet every demand of the medical societies in New York for some years to come. It is

not certain, however, whether the Academy and its sections will absorb most of the other societies, or whether the other societies will consent to hold their meetings in the rooms of the Academy, paying therefor a moderate rental. Some might fear that the importance of the independent societies would be overshadowed by the Academy if the meetings were held in that building. Besides, there is a social feature which would seem to be better met in special societies, such as the practitioners, medical and surgical, clinical, etc., by holding the meetings, as in the past, at the private residence of the members, a collation being served after the scientific proceedings. The new hall of the Academy, however, has every accummodation for societies which may wish to make it their home. A finer neighborhood could not be found. On each side and in front magnificent buildings are being erected, one for the Century Club, one for the Racket Club and one a hotel.

At the meeting referred to, Dr. Charles McBurney read a paper on skin grafting after the method of Thiersch, and cited twenty-five cases of extensive ulcers, burns and open surfaces in which he had practiced it with almost uniform success. He made the grafts as thin as possible, taken usually from the thigh, an inch wide by four or five long. The raw surfaces, however large, had usually been covered by skin in less than a month. The cases included epithelioma, cancer of the female breast where the flap could not be made to cover the entire gap, old ulcers of the leg, burns, etc.

Dr. Prince A. Morrow brought out an interesting modification of skin grafting. A man had sustained a burn on the head when a child, but was little annoyed by the resulting scar until recent years, when the surrounding hair began to fall out. He then became somewhat hypochondriac over his appearance, and Dr. Morrow determined to try an experiment for his relief. With the cutaneous spoon-trephine he took buttons from the sound scalp on the opposite side, going through not only derma but also subcutaneous tissue, including the hair follicles, and transplanting four of these immediately into holes of the same size made with the same instrument in the cicatricial tissue. He was gratified to learn that they united within a week, and after several weeks hair grew. Like success in this case attended the transplantation of grafts from another person. The method opened up a new field. It would be applicable, he thought, in the removal of moles from the face which people carried through fear a scar might remain if they were excised.

New Yorkers seem a little jealous for the reputation their city has had of being the metropolis of the country, and notwithstanding they have a good deal to say about how foolish some poor people are in remaining in so crowded a place when there is plenty of room in the West, yet they are anxious to have the Census Bureau give them credit for all the inhabitants present. The truth would seem to be that our citizens are awaking to the need of doing something to prevent our commercial supremacy from slipping away, and probably nothing has done more to impress this need upon them than the growing importance of the West, brought out more prominently by the influence of Chicago in the World's Fair matter. Spurred probably by these reflections and others, a commission appointed by the Legislature is holding sessions on the advisability of uniting to New York Brooklyn, with a population of over eight hundred thousand, Long Island City, with a population of thirty thousand, New Rochelle, etc., to the north, and Staten Island to the south. For commercial reasons (the bridging and tunneling of the rivers, etc.) this would doubtless be very desirable, but there are sanitary reasons as well. Long Island City, for instance, separated from the middle and upper part of New York by the East River, only half a mile wide, remains largely vacant ground, for the reason, doubtless, that it has the reputation, only partly deserved, of being a place of misrule, bad smells from oil works and swamp meadows. Improvements by bridges, tunnels, etc., made on a scale becoming a great united city, would make of this a most accessible and healthful place for business and residence.

Under the pretext of appearing to have a larger death-rate per thousand than is the fact because of the under-estimate of our population by the superintendent of the census, the Board of Health and city authorities have instituted a recounting. It is believed the population is over eighteen hundred thousand, instead of sixteen hundred and odd thousands as made out by Mr. Porter. But however great the population may be, until recently it could not compete for magnitude with the filth of the streets. I say until recently, for during the past two or three months the politicians have been

spurred, by the prick of the public press and the fear of a proposed independent citizens' movement, to expend a part of the immense appropriation for street cleaning in really cleaning the streets. But this is not likely, judging from past history, to continue longer than the fall elections.

One improvement which cannot be too highly estimated is the paving of a number of the cross streets, and Madison and Lexington avenues, with asphalt. It is said there has been a great steal back of it, but the citizens have something of real value to show for the theft, which cannot be said for all the frauds perpetrated by the politicians.

Speaking about the independent citizens' movement for better local government, I saw the names of a number of prominent physicians in the list of delegates to the recent convention, among them being Dr. Loomis, Dr. A. Jacobi and Dr. Landon Carter Gray whose head is said to be the highest of any physician's in the city considering that it is also an extremely large one in circumference, measuring nearly twenty-four inches. The movement is an earnest one, and, with such an amount of brains back of it, will commit no folly. The question of whether candidates will be placed in the field will, probably, depend upon the character of the nominations by the old parties, especially Tammany Hall. It is believed, at any rate, that the Australian system of voting and some other facts are conspiring to bring about some needed reforms in this city, which will make it healthier and more desirable as a place of residence as well as increase its commercial importance. One of the most pressing needs has been fulfilled since the opening of the new Croton aqueduct, by which we are now able to get water even on the top floors of nearly all buildings.

R. C. S.

NEW YORK STATE MEDICAL ASSOCIATION; SEVENTH ANNUAL MEETING.

The seventh annual meeting of the New York State Medical Association was held October 22–24, in Mott Memorial Hall, New York City, a building which the Association has recently acquired as a permanent home for its meetings and library.

The Secretary, Dr. E. D. Ferguson, in his annual report, made pointed reference to the action of Governor Hill in respect to the New York State Medical Examination Bill. The speaker represented the bill as having been rushed through at the end of the session. When it became generally known that it had passed, contrary to all expectation, hundreds of telegrams, and every form of remonstrance was brought to bear upon the Governor to stay his signature upon the ground that the bill was unjust and one-sided. The Governor had replied that he must assume the bill had been well considered in committee and that if the doctors did not like it they could send up another in a modified form next year.

The President, in his address, dealing with the question of medical education, said that while upholding the principle that medical colleges should demand proof of adequate preliminary education from would-be students, he was not prepared to say that the possession of academic degrees should be made a *sine qua non* of qualification to commence the study of medicine. He did not believe that the colleges of this country were below par, indeed there was every evidence of a steady raising of the standard of excellence in the educational material. The fault had been, and still remained, that colleges had opened their doors to inadequately prepared students. In speaking of the medical press of the country, he said it had assumed a proportion and weight of character unequalled in any other branch of literary science or art. To-day a subscription to a reliable medical journal was an investment which would repay with interest many times compounded.

Dr. A. P. Dudley, of New York, in a paper on the Surgical Treatment of Recto-displacements of the Uterus, described a method which he has recently carried out, and so far with excellent results, in four cases. He detailed the steps of his operation upon a case in which there was cystic degeneration of the ovaries. Briefly stated, his method is to open the abdomen, draw out a tube and ovary, puncture and squeeze out the cysts and allow the sacs to fill with first blood. Each ovary, if both are cystic, being so treated, they are dropped back. The uterus, being then drawn well forward, is denuded of its peritoneal covering on its anterior surface, the denuded area being oval. Then each round ligament is brought up and freshened to correspond. With a continuous suture of catgut the denuded surfaces are sewed together and the uterus is then dropped back.

Traction on the round ligaments now restores the organ to a position of anteversion. Dr. Dudley claims that the malposition is rectified without sacrifice of any of the structures, and that the result is accomplished without fastening the organ to the anterior abdominal wall, only its natural supports being used. No interference with the bladder need be feared, and in case of impregnation the uterus would be free to lift in the abdominal cavity. The tapping of the ovaries had caused no trouble and when it could be demonstrated that the tubes were pervious, he thought that the ovaries—now too often sacrificed — might in many instances be saved.

A long discussion on intra-cranial lesions served to demonstrate the fact that while the interest in the question of cerebral topography, with indications for operative treatment, and on the technique of operation is unabated, very little new ground has been broken of late.

Dr. C. K. Mills, of Pennsylvania, thought that the causes of failures and sources of error in dealing with the lesions resulted often from giving undue weight to a class of symptoms which were regarded as determinative of the site of the lesion. The motor signal symptom has been made use of on a large scale, but was often quite misleading. In every unilateral or mono-spasm, whether reflex, dural, nephritic, toxic or hysterical, the spasm really or apparently began with an initial symptom in the limb or face. This might indicate that the beginning of the cerebral discharge occurred in the area of the cortex, which was the seat of the representation of the movements, but it would be unwise to operate with such indications. Occasional conjugate deviations of the eyes and hand had been used as a guide. This was an error into which a thoughtless or ill-informed neurologist might lead the surgeon. The motor symptoms were often only the result of a diffusion of the lesion to the motor areas. In not a few cases of cerebral abscess, sensory or special symptoms might indicate the need of interference, but might not point to the proper site for the operation. All active localized symptoms of the brain, the result of mastoid, or aural disease, unless it was word-definite and left-sided affections, were the result of purulent processes. It was an error in the majority of cases to operate guided by localizing phenomena. In most of the spastic and paralytic congenital and early infantile affections. The greatest success so far seemed to have attended trephining for endocranial hemhorrhages.

Dr. J. D. Bryant thought that a small and presumptively circumscribed injury of the brain substance at the upper end of the fissure of Rolando might incite an advancing cerebral disintegration, sufficient to involve the motor centres associated with this fissure without causing notable constitutional symptoms. Aspiration of the brain as a means of diagnosticating the existence or situation of an abscess, he regarded as a measure of uncertain utility. He thought extensive fissure could begin at some distance from the point of violence causing it, and that its existence might remain unrecognized without an extended exploration. Extensive and fatal vascular complications might be caused at a considerable distance from the seat of an apparently innocent injury of the scalp or skull. When paralysis involving the motor area of the brain, followed a seeming trivial injury of the head, an operation at the seat of the injury was indicated for the purpose of exploration alone, but removal of a compressed brain clot was not necessarily followed by improvement in the symptoms of compression. If the brain did not soon resume its normal relations with the skull death would ensue.

Dr. W. W. Keen, thought that if a lesion could be located and differentiated from other conditions which might produce more or less similar phenomena, and the general indications were such as pointed to the necessity for interference, then the head should be opened. The head had too long been regarded as something apart and different from other portions of the body. He would urge that it should fall into line with other cavities of the body, subject, as it was, to the same diseases and injuries. The treatment might be modified in detail, but should be the same in principle.

An entire session was devoted to a discussion on obstetrics, every point of debatable ground being covered during discussion. Every phase of theory and practice as to the management of the parturial period, obsolete and advanced, found some advocate whose alleged experience seemed to entitle his opinions to unqualified respect to the exclusion of each of the others.

Dr. G. T. Harrison, of New York county, thought that the internal examination of the lying-in woman might be very well dispensed with, or compensated for by external

methods. The same speaker thought that auto-infection, by streptococci invasion of the natural genital secretions, impossible. Vaginal douches should not be given before, during or after the birth. He would employ no manipulative procedures in dealing with the placenta as a whole, though he thought such might be employed with reference to retained portions of decidua. In the same paper this speaker emphasized the importance of ocular confirmation that there was no tear.

Obstetricians of such recognized experience as Dr. S. B. Wylie McLeod and Dr. Darwin Colvin held views and had experiences diametrically opposed as to the removal of, or non-interference with, the placenta after the second stage in abortion. The former had never seen a death from sepsis traceable to retained secundines, while fifty years out of the professional life of the latter observer had been embittered by a fatality, the direct result of failure to carry out what was now his rule, never to leave the parturient chamber until the entire placenta was in his hands.

Dr. W. McCollom thought that between two extremes there was always a golden mean. He would therefore suggest that all medical students should be instructed that, when, in practice, they were called to a case of obstetrics, they should first take a Russian bath, have their hair cut and shampooed and buy a new suit of clothes. On entering the lying-in chamber the physician should, if he had touched the door knob, plunge his hands into a strong solution of carbolic acid or bichloride. Then he should have a steam atomizer casting a spray that would act like a Gatling gun on any bacilli which might have come in out of curiosity or with fiendish intent. The bacteria must then be dug from the finger nails and thrown into the fire. Then after again washing his hands in bichloride this chemically pure accoucheur might make an examination as soon as the lady said the child was coming. The lady should have a constant stream of bichloride thrown on to the genitals or have the nates immersed in a tub, fitted to the bed, full of the same material. If the child, when born, should happen to swallow any of the fluid it might serve to destroy any bacilli of which it might have inadvertently partaken in utero. Of course no competent practitioner would allow the child to drown in the tub. Breach presentations require special care and a sterilized cork should be adjusted within the sphincter and to prevent the meconii-cocci from escaping too soon. On delivery a bichloride pad should be placed to the genitals and hermetically sealed, and not be removed unless under light antiseptic precautions. The speaker, whose remarks were received with roars of laughter, then said his hearers might perhaps think him frivolous, but he had listened to almost as ridiculous instructions from the highest authorities. As a matter of serious fact, let it be an invariable rule to have the *entourage* of the patient as clean as possible. This was the best safeguard against sepsis in whatever complications might arise.

The miscellaneous papers recited little that was new and much that was very old. Dr. H. O. Jewett, of Cortland county, N. Y., made a trite but rhetorical appeal for the more general recognition of phlebotomy as a therapeutic measure.

Dr. Stephen Smith, of New York, the newly-elected President of the Association, read a fine historical paper on the ligature of arteries, developing the statistical fact that American surgeons had been prominent, and in some instances pioneers, in the bolder and most surgically-difficult ligaturing of the larger arterial trunks for the cure of aneurisms.

The *vexata questio* of hypnotism was ably spoken to by Dr. E. Shmid, who dealt with its practical utility in certain diseased conditions. Dr. Dudley recalled the case of a young lady with a bad cough, which nothing could allay. It was at length determined to play upon her religious sympathies. Holy water was prescribed, or what she was told was holy water, a teaspoonful every half hour, and a speedy cure effected. He had just learned from the scientific exposition by Dr. Shmid that this was hypnotism. He often gave water instead of morphine and it did just as well. He was quite prepared to admit that these were mental conditions beyond the control of the patient.

—Women druggists seem to be very few, considering the extent to which members of the sex have engaged in other professions. A Chicago druggist, recently interviewed, knows of but three in that city. One of these is a woman who has charge of the store owned by her husband. He says he does not know why there are not more women in the drug business. It seems that there is a field for them here.

PERISCOPE.

College Athletics.

Professor W. M. Sloane, in *Harper's Magazine* for November, says: The subject of athletics as a permanent element in school and university life should be viewed from several aspects. The first one is trite enough: that, as patriots and educators, college managers are bound to provide physical education as well as moral and mental. This is admitted on all hands; the question is how to reach the result. Some would have military drill, discipline, and uniforms, with an instructor from the officers of the regular army, as provided gratis by the general government. Others would take the dimensions of every limb, the proportions of the body, and auscultate for every defect in lungs and heart, and then, under medical supervision, provide the apparatus needed to expand the chest, or draw down a shoulder, or decrease the waist and send the young Apollo with his perfect proportions and graceful walk on his journey through the world. A third method is to provide a free gymnasium, also with a competent instructor, leaving its use in preparation for sports of various sorts to the option of those who engage in them, or wish to, and provide a stimulus for the largest possible number to use it by the development of the glorious and exhilarating out-door games—base-ball, foot-ball, lacrosse and rowing—in the management of the students themselves.

It is clear that the first of those propositions would add a new study to the student's already overburdened course, and emphasize unduly the military conception of life in our civil institutions. The second must go down under the simple consideration that it makes work out of play, and like the former destroys all spontaneity and initiative on the part of the student. If military drill and gymnastic exercises are really a portion of a liberal education, make them so openly, incorporate them in your scheme, but still leave time for recreation. The third one, therefore, is the correct conception. We firmly believe in the value of physical training, but athletics is quite another thing, for it includes the moral element in the conduct of sport, which is second to no other.

The time of college years is too precious to be devoted to the work of mere physical training. Yet recreation is essential. When young men, therefore, play from the love of it, they get both. And as intercollegiate sports were managed for many years, they get far more, namely, the experience of large enterprises; the character of generous submission to defeat, with perseverance to begin all over and try again; and self-restraint, with courtesy to the weaker, in victory. This was so when out-door sports were conducted for the sake of sport, as they once were, and will be again when the true bearings of harmonious co-operation and pluck upon winning shall be rediscovered. It is certain that in the intense rivalry of such contests victory will go only where fine traditions are guarded, and spirit perpetuated by the active interest of every man according to his powers. Any in-door recreation or exercise, while it has its place, is, after all, a poor shift for out-door sport. It is a serious truth that other nations wonder at the proud position of the Anglo-Saxon race, and that they attribute the fine ripe qualities of maturer life to the beginnings born on playing fields and matured in the seriousness of conflict. These mimic battle-fields demand the same qualities as real ones, and no great game is won without the moral support of the non-combatants. Union, organization, enthusiasm, pluck, high principle—every one of them is as much the price of athletic as of martial victory. It is humiliating, when we have the precious possession of taste and power in such a matter, to find it belittled and discouraged in so many ways. Instead of being grateful for the Spartan element in the training of its youth, America is either ignorant of its value or opposed to its exercise entirely.

Sexual Life of Women after Castration.

Dr. F. Keppler, of Venice, presented a paper at the Medical Congress at Berlin, embodying the results of a study he had made in the cases of ovariotomy performed by him. As reported in the *Medical Record*, September 20, 1890, he has performed castration of women 46 times, obtaining a cure in 39. These operations were performed for the relief of purulent or gonorrhœal salpingitis, oöphoritis, fibroid tumors of the uterus, etc. The following were his conclusions, derived from a study of the physiological consequences of these operations: 1. When the operation was performed on account of sal-

pingitis or other inflammatory process, uterine hemorrhage never occurred subsequently. 2. The conjugata become gradually shortened, and this was the more marked, the younger the individual was when operated upon. 3. The uterus became atrophied, the vagina grew shorter and narrower, its mucous membrane became paler, and the labia majora were somewhat thinned. 4. The breasts grew smaller, acquiring a strong resemblance to the male mammæ. 5. The brown pigmentation of the nipple, areola, perineum, and anus disappeared wholly, as did also pathological pigmentation existing in some of the cases; the hair also turned white. 6. The tendency to embonpoint, which is generally believed to exist after these operations, was not observed by the author. 7. No changes were observed as regards the growth of the hair or the tone of the voice. 8. The sexual desire remained, and was the more pronounced the earlier in life the operation was performed. 9. The operation offers no impediment to marriage; three of the author's cases had married and had lived happily with their husbands for years. 10. A marriage with a castrated woman is the ideal Malthusian marriage, and the only way the Malthusian idea can be carried out without endangering the health and happiness of the woman. 11. In the cases operated upon in early life for inflammatory conditions, no neuroses were seen to develop, which was not the case when women were operated upon late in life for fibroid tumors of the uterus. 12. A favorable influence upon the hemorrhage was observed after operations for myoma, yet in no case did the menopause at once set in. 13. In cases of operation for uterine fibroma, the patients, even those in full maturity, lost all sexual inclination after the operation.

Brain Surgery.

In a paper on Surgery of the Ventricles, read at Berlin by Dr. W. W. Keen, of Philadelphia, *Medical Record*, Sept. 20, 1890, he concluded that injuries involving the ventricles, the result of a compound fracture or of trephining, and involving great disturbance of the cerebral substance, are not necessarily fatal; for ten of the twenty-six cases he reported had recovered. In these cases compound fractures and extensive injuries seemed to be less dangerous than rupture of the ventricle from simple fracture. Dr. Keen said they should be treated antiseptically in precisely the same manner as are wounds in other parts of the body. If pus forms, or the cerebro-spinal fluid becomes dammed up, causing symptoms of pressure, incision and free drainage should be resorted to.

In cases of simple fracture involving the ventricles, Dr. Keen thinks it wise not to attempt any operative procedure unless threatening symptoms supervene. If necessary to interfere, he recommends that the cyst containing cerebro-spinal fluid should be continuously and slowly drained with a small bundle of horse-hairs, rather than by free evacuation. He believes in the majority of cases constant pressure and little active treatment would meet such symptoms as might arise. Possibly slight pressure would be all the treatment that would be necessary.

Abscess of the brain bursting into the lateral ventricle has been thus far uniformly fatal, and demands the promptest treatment possible. He thinks bilateral trephining and irrigation of the ventricles can do no harm, although the possibility of its doing any good is but slight.

Surgical procedures for tapping the ventricles for hydrocephalus are easy, and do not involve great danger. Whether or not they will cure the disease is not yet settled. In acute effusions tapping, with or without drainage, will save some lives otherwise doomed to be lost; and in the chronic form, long continued slow drainage at an early period is worthy of a trial, and offers a reasonable hope of success in a few cases.

After trephining and tapping of the ventricles, irrigation of the ventricular cavities from side to side is not only possible, but does no harm. In abscesses involving the ventricle, and possibly in other conditions, it may do good. The fluid used for such irrigation should not contain anything which, if retained and absorbed, might do harm. An artificial cerebro-spinal fluid, or a simple boric acid solution, seems to Dr. Keen to be the best for such use.

Convulsions, due to too rapid withdrawal of cerebro-spinal fluid, may be checked by the injection of an artificial cerebro-spinal fluid. In either irrigation or injection of the ventricles it is desirable that air should not enter; but air does not seem to do any harm.

In hemorrhage into the lateral ventricles, at least of a traumatic origin, Dr. Keen thinks that immediate trephining and evac-

uation of the clot should be done, and that in some cases this will probably be followed by a cure.

Oxaluria and Oxalemia.

It is a question whether the more or less constant presence of an excess of oxalates in the urine constitutes a disease *per se* or is but a symptom of some more remote condition. In the absence of a known cause we may apply to the manifestation the qualification idiopathic, just as in the present state of knowledge we do with regard to anemia and epilepsy. In the *Münchener Medichinische Wochenschrift*, August 26, 1890, Dr. Neidert refers to two cases, reporting one in detail, the symptoms of which he associates with the existing oxaluria and, to use his designation, oxalemia. In both cases one of the parents was diabetic. The nervous symptoms were the most prominent. There occurred paroxysms attended with severe cardiac palpitation—especially at night, a distressing sense of oppression and asthmatic seizures. Restlessness was marked. There was tremor, choreiform movements, and a staggering gait. Nervous dyspepsia made an additional complication. An attack of syncope was followed by increase of already excessive thirst, and by failure of appetite. Frequent examinations of the urine, which was passed in large amounts, failed to reveal the presence of sugar; but oxalate of lime was found in amounts out of all proportion to the amount and kind of food taken. There was loss of flesh and strength. Investigation permitted the exclusion of acute or chronic disease of the stomach.

The view of Neidert is that in oxalemia there is an abnormal production of oxalic acid from the tissues of the body, owing to alterations in the central nervous system. In connection with the influence of heredity, he believes, in his case at least, that the oxaluria is only a preliminary stage of a diabetes.

Secretion of Milk in the New-Born.

P. G. Variot made some remarks on this subject before the *Société médicale des Hôpitaux de Paris*, July 25, 1890. He is convinced that it is not in the first days which follow birth that the secretion of milk is most abundant, but generally on the eighth or twelfth or even the fifteenth day. At this time the glands jut out like two small watch-glasses applied to the chest, and, when the milk has not been evacuated, the mammary region is raised, forming a small, round tumor the size of a hazel-nut. The skin covering the gland is often reddened. Palpation gives a sensation of puffiness. Pressure to squeeze out the milk is painful, as it would be in a wet-nurse with engorged breasts. It is known, he says, that the development of abscess of the breast in the new-born is by no means less frequent than in a woman who is nursing, and that in each case a good way to prevent it is to empty the milk ducts. [A dangerous suggestion.—Ed. Reporter.]

On compressing the gland slightly when the secretion of milk has been well established, that is to say at from the eighth to the fifteenth day after birth, it is not rare to squeeze out two or three cubic centimeters of a liquid which presents all the external characteristics of milk. Chemical analyses made at the instance of Gübler have finally proved that the milk of the new-born contains all the principles essential to the milk of an adult woman—in proportion a little less and a little variable, it is true. This agrees substantially with the analyses which he had made by Lecocq. Thirty-two children, girls and boys, varying in ages from three days to nine months, were examined for the presence of milk. It was present in all but six, of course varying in character and amount. He concludes, therefore, that this function in new-born children is a constant occurrence, though it is only temporary in duration. Emaciation, and even extreme cachexia, do not not appear to exert any checking influence upon it, as these conditions are well known to do in women.

Retarded Syphilis.

Dr. Brocq writes to the *Journal of Cutaneous Genito-Urinary Diseases*, September, 1890, that Dr. E. Besnier has insisted quite recently in his clinics upon a fact quite common but of great practical importance. Recently a young man presented himself for consultation at the hospital with an indurated lesion of the lip having all the characters of syphilitic chancre, accompanied with a retro-maxillary adenopathy, which confirmed the diagnosis. Nevertheless, the patient would not admit that he could be syphilitic; for he contended that he had not been exposed to any contamination. The treatment was postponed in order to convince

him by the appearance of secondary phenomena. At the end of three months' observation nothing had been developed.

The conduct of such a case is most delicate. A diagnosis of syphilis seems indubitable, and we know that sometimes roseola may not manifest itself until quite late; it may be retarded until the sixth month, as Ricord has demonstrated. We know also that a chancre having all the characters of a syphilitic chancre may never be followed by general accidents. Should we nevertheless institute specific treatment, or await the development of other symptoms denoting a general infection of the economy? Dr. Besnier believes that this latter practice should be adopted only in the presence of really doubtful cases.

The Bites of Spiders.

A good deal of doubt exists as to the possibility of the bite of the spider determining in a fatal result, although plenty of alleged cases are on record in ancient literature. Several more recent cases have been published at different times in *Insect Life*, a monthly periodical published by the Entomological Service of the United States. Most of these cases are ascribed to the *latrodectus mactans*, an American spider, bearing a strong resemblance with the *latrodectus magmigniatus*, or genus met with in Southern Europe, and particularly in Corsica, where it has been accused of inflicting fatal injuries. In the first of the cases quoted in *Insect Life*, death is alleged to have taken place in fourteen hours, the victim being a man in perfect health. The pain was extremely violent; there was hard œdema of the arm and neck, and death was preceded by coma. In six other cases recorded by Corsen, of Savannah, the symptoms, though severe, did not terminate fatally. Four of the victims belonging to this series were bitten during defecation, and in addition to the pain, tetanic spasms were noted, lasting several hours, respiration being dyspœnic and the pulse rapid. Unfortunately for science, the insect could in no instance be identified. The symptoms were the same as those embodied in the report drawn up by M. Graells for the Academy of Medicine of Barcelona in 1833, on the effects of bites inflicted by the malmignate. This observer insisted on the sense of constriction in the throat, tenesmus, opisthotonos and general tetanoid convulsions followed by loss of consciousness. In New Zealand there is also a spider, the *latrodectus scelio*, which is credited with similar powers, attacking persons engaged on the seashore, but the effects are narcotic rather than tetanic. Usually the use of morphine hypodermically and the administration of stimulants have averted a fatal issue even in serious cases, but the treatment is purely empirical, for as a matter of fact, little or nothing is known of the nature and physiological action of this class of toxic agents.—*Medical Press*, September 3, 1890.

Strychnine as an Antispastic.

In the section for neurology and psychiatry of the International Medical Congress, at Berlin, August, 1890, Dr. Benedikt, of Vienna, read a paper on strychnine as an antispastic. He was led to employ it for this purpose through noticing its effects in a case of chorea minor in a girl twelve years old. The patient had received previously other medical treatment, and treatment by electricity and hypnotic suggestion, but without result. The disease manifested itself as a mimic chorea consisting of disagreeable snapping movements, and by convulsive movements having the character of chorea minor and affecting the extremities. Strychnine subnitrate, in doses of one-twentieth of a grain, was ordered in pill form from three to five times a day. The effect upon the facial movements, which had the character of chorea major, as well as upon the other convulsive movements, was striking, and the patient was cured as the result of this medication.

Benedikt says that at first he was surprised, but on second thought still more surprised at his surprise, for he has known for twenty-five years that paralysis and spasm are not antithetical, that irritation of nerve centres and paths produce spasm, while destruction of the same causes palsy, and that the designation of convulsions by Romberg as hyperkinesis is erroneous. Convulsions are rather symptoms of disease of the centres and conductive paths, which have nothing to do with voluntary movements in the proper sense—that of Sir Charles Bell. Moreover Benedikt says he has always emphasized the fact that in the majority of cases of convulsive conditions, there is not a state of irritation of the convulsive centres and conductive system, but, on the

contrary, one of aplasia, atrophy and destruction of this system. Hence it is not astonishing that an agent which in the physiological state excites convulsions, cures convulsions if they are produced by a condition of lessened nutuition of this system.

Since Benedikt's first success with strychnine in chorea he has experimented with it, and has obtained favorable results—although not with great constancy—in forms of chorea major, especially in the phonetic-respiratory, and in general in those cases which are to be regarded as neuroses without lesion.

Dislocation of the Testicle.

Mr. E. H. Howlett writes to the *British Medical Journal*, September 13, 1890, an account of an accident of such rarity that it is well worth repeating his story here.

A man 65 years old, four years before Mr. Howlett saw him, in 1886, at the Infirmary, had been knocked down by a cart, the wheel of which passed obliquely over the left side of the abdomen, crushing the scrotum.

On making a careful examination, in addition to the spinal symptoms, for which he came for treatment, Dr. Howlett found the following extraordinary condition of the genitals. The right testicle was in its place and healthy, the left was absent from the scrotum, but was found lying on the left side of the body of the penis. The epididymis was drawn up close to the external ring, and was felt to be connected with the testis by a cord, which to the touch gave the sensation of a normal vas deferens. The testis itself seemed healthy, was of good size, and tolerably firm to touch, whilst pressure upon it caused the usual testicular sensations. There was no doubt either on the part of the patient or Dr. Howlett, that the body on the side of the penis was the left testicle. It gave rise to no inconvenience, as Dr. Howlett was given to understand that for some time the penis had been limited in its functions to those of an aqueduct.

Prohibition of Hypnotic Performances in Russia.

The *British Medical Journal* states that the Russian Medical Department in August, 1890, issued a circular which declares, "in consideration that public exhibitions of hypnotism cause considerable injury to the health of subjects experimented upon as well as of spectators witnessing the experiments, the performances being apt to give rise to the development in hypnotized persons of various hysterical, nervous, and even mental affections, which may sometimes amount to a genuine epidemic of hypnotic mania; that such public hypnotic entertainments offer to evil-minded persons a good opportunity for studying methods of hypnotizing, and for subsequently practicing them for various immoral or criminal purposes; that generally such hypnotic performances, being not accompanied by any rational explanation, can breed in the public only erroneous notions and even implant superstition, while post-hypnotic suggestions can constitute a source of disturbance of order and the place of the community by hypnotized persons, and even of committing criminal deeds by the same, the Medical Council has resolved: That henceforward any public *séances* of hypnotism and magnetism are strictly prohibited; and that the application of hypnotism for medical purposes can be permitted solely to medical practitioners, under the condition that the operation is to be practiced invariably in the presence of other medical men."

Pemphigus Neuriticus.

Zmigrodsky, *Bolnitchnaya Gazeta Botkina*, May 30, 1890, reports a case of pemphigus, which he thinks is rather rare as regards the etiology of the affection. The patient sustained a fracture of the femur and an injury to the sciatic nerve; she was subject after that to neurotic pains along the course of the latter, and at different intervals —twenty-three times during ten months of observation—had the characteristic pemphigus eruption along the peripheral branches of the stiatic nerve. That pemphigus was of neurotic origin in this case, the author believes to be proved by the fact that the patient suffered intense pain in the parts just before the eruptions occurred; that the muscles of the injured limb were undergoing progressive atrophy, and there was anæsthesia of the limb.

Though unable to give more scientific proof of the affection being neurotic, author is convinced that it was due to nerosis of the peripheral nerve branches.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

EXCISION OF THE RECTUM WITH PRESERVATION OF THE SPHINCTER OF THE ANUS.

The treatment of malignant disease of the rectum has always presented great difficulties on account of the inaccessibility of the part. When the disease has been too extensive and too high up to make removal by the anus possible, the usual practice has been to approach it from the front, by opening the belly, and, after excising the diseased part, to make an artificial anus in the iliac region. It frequently happened under this method that the patient passed through a critical operation (or he did not), and in the end had only a miserable existence. In 1885, Prof. Kraske, of Freiburg, proposed to approach the disease from behind, by cutting down to the coccyx, separating it, and, if necessary, chiselling away part of the sacrum. In this way it is possible, after excising the diseased portion of the rectum, to unite the upper healthy portion of the rectum to the preserved sphincter of the anus. The preservation of this muscle makes the life of the patient comfortable; without it he is miserable.

In a communication to the Société de Chirurgie, of Paris, May 28, 1890, Dr. Paul Reclus reported a case of cancer of the rectum in which he had excised the rectum and had succeeded in preserving the sphincter with its functional activity. The patient was a man, forty-seven years old, vigorous and robust. The cancer extended to within about two inches of the anus, and measured not more than one and one-half inches in one direction by two and one-third inches in the other. Infiltration had not gone beyond the mucosa, and the tumor was entirely movable, without any adhesions to the pelvic organs; it was therefore a favorable case for operation. Dr. Reclus followed Kraske's method by cutting posteriorly down upon the coccyx. The separation of the periosteum of the latter and of the sacrum gave rise to profuse hemorrhage, but this was controlled with tampons. The incision gave access to the rectum after exsection of the coccyx and one sacral vertebra. The indurated portion of the rectum was then removed, the incision extending for about one-third of an inch into the healthy tissue. Search was made for enlarged glands, but none were found. The upper end of the bowel was then drawn down and united by sutures to the sphincter, after being reduced in circumference like the mouth of a purse, so as to accommodate its larger caliber to that of the sphincter. The long ends of the sutures were carried out through the anus. A large drainage-tube covered with gauze, as recommended by Poncet, of Lyons, was inserted into the rectum to facilitate the passage of gas. The posterior incision was then sewed, only an open space for safety, stuffed with iodoform gauze, being left above the sphincter.

The result of the operation was excellent.

The temperature never rose above 99.5° Fahr. A fistula was feared, but it did not form. Immediate union was obtained. On the tenth day the tube to facilitate escape of gas was removed, and the patient was purged. In less than four weeks the patient went home entirely well.

This operation, as Reclus very justly remarks, is better than one resulting in an artificial anus; for in the former the patient has control of his stools. But it cannot be performed when the cancer is very large and adherent; for extirpation is then very dangerous and, if it does not result in the death of the patient, only gives him the equivalent of an artificial anus. It is better, therefore, when the cancer is large and adherent, to form an artificial anus at once, as the mortality of the operation for this purpose is, at the present time, almost zero.

AN ALLEGED ABORTIONIST.

The MEDICAL AND SURGICAL REPORTER, on May 1, 1890, called attention editorially to the case of a physician in Easton, Pa., who was suspected of being an abortionist, and published an account of an interview held with this physician by a representative of the REPORTER and certain letters which had passed between them. This publication was followed by the indictment of Dr. Fackenthal for criminal abortion in the case of a young woman, and he was recently brought to trial before the Northampton County Court. The defense attempted to prove that this girl visited the doctor's office for the purpose of ascertaining whether she was pregnant; in which case her lover had promised to marry her. Her first visit was made on February 26, 1890, when, as she stated, she was examined by means of an instrument which was identified as a Fergusson speculum. She also stated that she experienced a sharp cutting pain. Her testimony was not clear as to whether another instrument was also used, though at times she would admit that an instrument like a uterine sound had been employed. The doctor testified that at this time he could not determine her condition accurately, but gave her a bottle of medicine, which subsequently was found to contain a solution of bromide of potassium. Her next visit was one week later, March 5. At this time she was also examined with instruments, and twenty-four hours later she was taken sick and sent for a physician, who refused to take charge of the case because he suspected, from statements made by the family, that Dr. Fackenthal had attempted an abortion. Dr. Fackenthal was accordingly called in, and treated the case until after the passage of the fetus, and in fact throughout the entire illness of the girl, which was at one time considered sufficiently serious to necessitate the calling in of an alderman, to take an ante-mortem statement. She however recovered after a prolonged illness. The fetus was preserved, and on examination was found to have a large ecchymosis on the head and also two small punctured and contused wounds on the trunk. A microscopic examination of these ecchymoses showed them to be certainly ante-mortem. The evidence, as produced by the prosecution on the trial of Dr. Fackenthal, showed that the girl had visited his office twice within one week—an interval too short to be of any aid in detecting any progress in a case of pregnancy; and that instruments had been used on each occasion—which would evidently not have been necessary in determining the fact of pregnancy, and that within two days after the last visit symptoms of miscarriage began. The girl herself was a very unsatisfactory witness and on cross-examination frequently contradicted her own statements. As she was one of the most important witnesses of the prosecution her testimony proved far from beneficial to this side of the case.

Some of Dr. Fackenthal's testimony was highly interesting from a medical standpoint. In trying to account for the injuries found on the fetus, he stated that in cases of

miscarriage so much force was at times necessary in delivering the fetus that he frequently pulled off arms or legs, or even the head in extreme cases. He also stated that if no instruments were at hand, he at times used a lead pencil, in connection with one of his fingers, as a pair of forceps, to further aid in the delivery; and if he had no pencil he was accustomed to cut a limb from a tree for the purpose. He asserted that the speculum was necessary for the diagnosis of pregnancy, and that it could be used to exclude other conditions that might simulate pregnancy by suppressing the menses, such as tumors (!) also, that he had practiced *ballottement* in this particular case, though the girl had been pregnant less than three months. He further said that the placenta was formed before the fetus.

The defense undertook to prove that a probe could not be passed into the uterine cavity through a Fergusson speculum, and produced Thomas's *Diseases of Women* as proof of this.

The letters written by the representative of the REPORTER and by Dr. Fackenthal—which were published in the REPORTER—were admitted by the defense to be genuine, and were of importance as bearing upon the general character of the latter, but did not pertain directly to this case.

The judge in his charge to the jury reviewed the evidence and instructed them that, if they were unable to convict the defendant on the evidence bearing directly on the offense named in the indictment, they should bring in a verdict of not guilty. He stated further that they were not to be guided alone by the evidence brought out by the MEDICAL AND SURGICAL REPORTER in the letters and reported interviews of its representative with Dr. Fackenthal. The judge also referred to the grave nature of the charge and the effect in case of conviction on the family of the accused. Under all these influences, the jury, after deliberating for about three hours, brought in a verdict of not guilty.

PSEUDO-TYPHOID BACILLI IN DRINKING-WATER.

The strong tendency of current pathological teaching to ascribe all infectious diseases to the action of specific germs or their products has led to an extensive study of bacteriology. In spite of the fact that this branch of medicine is so recent, its literature is enormous already, and what is not known of course vastly exceeds what is known. The germs being microscopic, their forms and size can help but little in differentiating one from another of the same group, and hence reliance has to be placed upon the shape, size, color and other characteristics of pure cultures growing in mass in a culture medium. It is possible to make mistakes even when these are observed, unless the person making the observations is unusually skilful. To illustrate this fact, we may refer to an article entitled "Notes on Pseudo-typhoid Bacilli found in the Waters of the Riviera," by Dr. Cassedebat, published in the journal of the *Société de Biologie*, June 29, 1890. Cassedebat has found in the waters mentioned three bacilli which resemble very closely the true typhoid bacillus of Eberth.

He gives in detail the points of similarity between the true and false forms, and also the points of difference. As regards the latter, it appears that cultures of the typhoid bacillus in milk give an acid reaction after four days, whereas two of the pseudo-typhoid forms give an alkaline reaction. Cultures of the bacillus of Eberth made on a one per cent. solution of peptone in an incubator, become very cloudy in a few hours and never present any other peculiar feature.

One of the false forms produces after the second day a fine pellicle without clouding the liquid, and a second false form both clouds it and produces a thicker pellicle on the surface.

Peptonized bouillon sowed with Eberth's bacilli, either at the temperature of incubation or at the temperature of the labora-

tory, are clouded more or less rapidly; while two of the false forms produce on the first day a thick pellicle, which in one case is very resisting and breaks up into lumps in the other.

In the incubator, cultures of the false typhoid bacilli in bouillon and in milk, when stained with the colors suggested by Nœggerath, give special characteristics more or less peculiar to each. These Cassedebat describes at length.

Enough has been said to justify the conclusion of Cassedebat, that when an investigator finds in water bacilli having the morphological characters of those of Eberth; when these bacilli form colonies similar to the latter; when this resemblance is continued in cultures on potato—even then, he ought not to assert that they are typhoid bacilli. It is absolutely necessary, before making such an assertion, to cultivate each of these bacilli and to compare the results with those obtained with the bacilli of Eberth.

The second conclusion of Cassedebat is also highly important. He says: "It is impossible to give even an approximate estimate of the number of typhoid bacilli which may be contained in a quart or in a cubic centimeter of water, for example, without having subjected to the same control experiment each one of the colonies resembling those of Eberth's bacillus."

The bearing which these observations of Cassedebat have upon the asserted presence of typhoid fever germs in drinking-water, when these assertions have been made by bacteriologists of only moderate skill and experience, or by chemists with no knowledge of bacteriology, is too clear to need further exposition. The lesson to be learned is, first, one of modesty on the part of those who make reports upon the unwholesomeness of water supplies, and, second, one of encouragement to those who have been slow to believe all the evils that have been said to exist in water that does not look pure.

A VETERINARY HOSPITAL.

The Veterinary Department of the University of Pennsylvania has opened a free clinic for animals needing veterinary treatment, and will maintain an ambulance service in connection with it. This will bring the admirable equipment of this Hospital within the reach of many who otherwise could not receive its benefits.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

LES ANESTHÉSIQUES. Physiologie et Applications Chirurgicales. Anæsthetics. Physiology and surgical applications. BY A. DASTRE, Professor of Physiology at the Sorbonne. 8vo, pp. xi, 306. Paris: G. Masson, 1890. Price, five francs.

Dastre has set himself the task of searching out the origin of anæsthesia, of exhibiting the facts and theories relative to the agents most commonly used—ether and chloroform—and of making known the long list of new agents which have since been added to the first.

As regards the relative safety of ether and chloroform, he says the former appears to be less dangerous than the latter in the first stage of anæsthesia, since the heart is less likely to stop before the respiration under the administration of ether than under the administration of chloroform. But he declares that the expression of a general and exclusive preference in favor of one anæsthetic is an error similar to that of the physicians who, without taking account of the indications, desired the French Academy, in 1833, to choose between blood-letting and purgatives in the treatment of pneumonia. There are some cases in which chloroform is proper; there are others in which ether is preferable. Ether, he says, should be preferred when, from the condition of the patient or other causes, secondary syncope is dreaded, or when a patient has a lesion of the right heart and of its orifices as a result of a chronic affection of the lung. On the contrary, in prolonged operations, or where there is a lesion of the left heart, or for children, chloroform is preferable.

There is a great deal to be said in favor of Dastre's views, and much could also be said on the other side. Patients have lost their lives, especially in abdominal sections, apparently from prolonged etherization. It seems to be true that, for children and in gynecological operations, chloroform is growing in favor. But many, at least in the northern and eastern portions of the United States, would not dare to give chloroform to a patient in whom any disease of the heart existed; while, on the other hand, it is regarded by some as preferable for persons with disease of the kidneys or atheroma of the cerebral vessels.

In general it may be said that when a surgeon has had large experience with a particular anæsthetic, he will have fewer accidents if he employs that one and no other. This one, whatever it be, is the safer *for him*.

Dastre's book is a timely contribution to a subject

now exciting the greatest interest, and as it is full of information it cannot fail of being welcome.

Literary Notes.

—The *Illustrated News of the World*, which is the American edition of the *Illustrated London News*, maintains its high character of literary and artistic excellence. It is especially strong in the direction of pictures and descriptions of scenery and life in widely separated parts of the world. Of late there have been a number of illustrations of ships of war of the various nations. The number for October 25, contains a very handsome representation of a Russian cruiser. The editorials by Mr. James Payn are always interesting, as might be expected of so shrewd an observer and so brilliant a writer.

—*Scribner's Magazine* for November is an extraordinarily beautiful and interesting number. To physicians articles of peculiar interest will be found in the papers on "Dr. Materialismus;" "The Training of a Nurse" and "A Day with a Country Doctor."

Notes and Comments.

Estimation of Nitrites in Drinking-Water.

Dr. J. C. Thresh, Medical Officer of Health for Chelmsford and Maldon, read before the British Pharmaceutical Conference, September 2, 1890, a paper on the quantitative determination of nitrites in drinking-water, of which the following abstract is contained in the *Chemist and Druggist*, September 6, 1890.

In carrying out a series of investigations as to the changes which take place in many waters when kept under favorable conditions, the want of a simple and rapid quantitative test for nitrites made itself felt. None of the ordinary processes answered the required purpose, and, therefore, the author was induced to attempt to make the exceedingly delicate potassium iodide and starch test an available colorimetric one. The experiments made with this object proved:

1. That with the same proportions of acid, starch, and potassium iodide, the rapidity with which the blue tint develops and the depth of the tint vary with the degree of oxygenation of the water.

2. The depth of color increases with the time of exposure, since the liberated NO acts continuously as a carrier of oxygen.

3. Temperature has a very appreciable effect.

4. Other things being equal, the stronger the acid and the larger the proportion of potassium iodide added, the more rapidly is iodine liberated.

5. The quantity and quality of the starch solution also affect the result.

6. When all the above factors are constant, then the rapidity with which the blue tint develops varies with the amount of nitrite present. To obtain satisfactory results it is, therefore, necessary to work with waters at about the same temperature, which have been well shaken with air, and have then been treated with exactly the same quantity of each reagent.

The reagents required are:

1. *Solution of Potassium Iodide and Starch.*

Starch (in powder)	2 grams
Caustic potash	1 "
Potassium iodide	2 "
Water	200 c.c.

Dissolve the starch in about 10 c.c. of water, to which the caustic potash has been added. Heating is unnecessary. The solution keeps well.

2. *Dilute Sulphuric Acid.*

	Parts.
Pure acid	1
Water	3

Mix.

3. *Solution of Sodium Nitrite.*

Pure sodium nitrite	.493 gram.
Water	1 litre

1 c.c. = 1 mlgr. nitrogen.

Apparatus required: a few small pipettes and 50 c.c. Nessler cylinders.

In making the analysis, shake the sample of water vigorously in a partially-filled bottle to saturate with air, pour 50 c.c. into the cylinder and add 1 c.c. of the starch and iodide solution, and afterwards 1 c.c. of the dilute acid. Stir gently. Assuming the temperature to be about 60° F., if a blue tint develops instantly on addition of the acid, the water contains more than 1 part per million of nitrous nitrogen. If the blue tint shows only after a few seconds, it contains about .1 per million. If it requires more than about 10 seconds to develop, it contains less than that amount.

In the first case the water is too strong for estimation, and it must be diluted with nitrite-free water in such proportion until an experiment shows that the color appears only after standing a few seconds.

With a little experience the approximate amount of nitrite present can be ascertained with considerable precision by these simple preliminary experiments.

Now prepare a standard nitrite solution by

diluting 1 c.c. of the above solution of sodium nitrite to 200 c.c. Each c.c. of this standard, diluted in the Nessler cylinder to 50 c.c., corresponds to .01 nitrogen per litre.

Measure into two or more Nessler glasses varying quantities of this standard solution, and fill up with the aërated water. Now take 50 c.c. of the water to be examined, or of the previously diluted water, if such dilution were found necessary, and add to each, successively and rapidly, 1 c.c. of the starch solution, and 1 c.c. of the acid. If none of the prepared solutions correspond in strength with the water fresh trials must be made.

The following are the notes on an estimation:

50 c.c. + reagents. Blue in about 10 seconds.

Compared with—

.10 per litre (10 c.c. standard dil. to 50 c.c.). This was a little too strong.

Compared with—

.05	Too weak.
.07	Too weak.
.09	Too strong.

Tried again with—

.08	Little too strong.

Estimated therefore at .075 N per litre.

Real strength was .070 N per litre.

Numerous determinations with all kinds of potable waters prove that the process is reliable. A determination only takes about five minutes as a rule. The reagents are easily made and preserved, and the conditions to be observed are easily attained. For the above reasons the author commends it to the notice of such analysts as desire to record the amount of nitrites in water examined. In the course of the paper Dr. Thresh mentioned that he had come across samples of water in which the nitrite fluctuated, and this it will be seen was a point which was considered in the course of the discussion.

Diet and Digestion.

At the last meeting of the Homœopathic Medical Society of Pennsylvania, Dr. M. S. Williamson, of Philadelphia, read a sensible paper on the Hygiene of the Alimentary Canal, in which he said that, in health, an excellent way to prepare the stomach for the morning meal is to take a drink of cold water, while for those who suffer with catarrhal dyspepsia hot water may be used to wash away the accumulated mucus to enable the gastric juice to act upon the food. In cases where there is loss of power of the stomach, and especially where there is irritability, hot water after eating is very soothing and beneficial.

It is not possible to lay down general rules for diet; each patient should be examined to ascertain what kind of food should be eaten. The mother's diet has a direct influence upon the unborn child, and may control the development of the bones and size of the child. Many mothers think that their milk is the best kind of food, but this is an error. In England it has been found that about ten per cent. of infants do not thrive on their mother's milk.

In the absence of mothers' milk, or in a case where this does not agree with the child, cow's milk must be given; or, if that cannot be digested, or if a good article cannot be procured, condensed milk; and there are many preparations of baby food that may be tried. In some cases where the mother has not enough milk to satisfy the child, it is right to urge the mother to retain her milk and to use the bottle for the additional meal, the notion that mixing milk is injurious having been found to be erroneous.

As a child grows it is necessary to add to the diet, and after a healthy child is nine months old it will require the milk to be given undiluted. When the child is a year old, bread or crackers may be added to the milk, but Dr. Williamson has found the best preparation to be oatmeal with milk. Boiled eggs and soups may be given at dinner, but light suppers are very important for the early years, and many children who have night coughs and bad dreams can have these troubles done away with by observing this rule. Not only young children but those of larger growth will feel much better in the morning, and eat their breakfast with more relish, if they take only food that is easily digested at supper time, and make it a rule never to eat anything after supper.

It is important not to sow the seeds of future trouble by allowing the use of condiments or of highly-seasoned food, for the time will come when there will be punishment for transgression. With advancing years, when the natural tonics of fresh air and out-door exercise cannot be taken, the use of malt in some form may stimulate the appetite. Meat is what is needed, and this

stewed and thickened with potatoes, barley, rice or split peas, forms a good food for the mid-day meal. Extract of meat and milk punch, in very old persons, may be given with advantage when they are not able to eat ordinary table food.

Thiol in Skin Diseases.

Prof. E. Schwimmer, Buda-Pesth, is cited in the *British Journal of Dermatology*, September, 1890, as recommending thiol as useful in erythema, dermatitis herpetiformis, herpes zoster, acne rosacea and acne vulgaris faciei, in papular and weeping eczema, as also in the treatment of burns, etc. It is generally applied in the strength of a one-in-three aqueous solution. Prof. Schwimmer was especially struck by the exceedingly satisfactory results he obtained with it in the treatment of herpes zoster and dermatitis herpetiformis. Of the latter disease a case had been ineffectually treated for three months with other remedies, but healed promptly in the course of a week when thiol was applied. The patient was painted regularly twice daily with the solution for two or three days, and the skin then carefully washed with pure water. It was found that the vesicles and bullæ had disappeared even in this short space of time, being replaced by scurfs of thiol, and the skin below showed nothing but a moderate pigmentation. A result like this appears really marvellous in such a refractory disease as dermatitis herpetiformis. In erythema exudativum multiforme also good results were obtained with the solution, but the thiolum siccum pulveratum seemed preferable, the eruption becoming much paler in three to six days, and soon healing completely. The liquid form again proved more adapted to papular eczema, being especially cleanly in application. On the whole thiol does not soil much, though the ointment form (made of 2 parts of thiol and 20 parts of lard) is not quite so agreeable as the solution. Its great advantage over ichthyol is, however, the absence of all unpleasant odor.

A Steam Milk Sterilizer.

According to the *Deutsche Medizinal-Zeitung*, Sept. 25, 1890, Dr. Schmidt, of Mülheim, in the *Archiv. für animal. Nahrungsmittelkunde*, No. 7, 1890, describes an apparatus for the sterilization of milk, which is thought to be simpler in construction and more useful than any hitherto devised. The essential parts are a shallow, concave vessel or boiler, to contain water, with a perforated cover surrounded by a rim of wood, to receive the bottles of milk, and a lacquered paper bell-shaped cover with an opening at the top for the escape of steam. The bottles are furnished with adjustable ground-glass stoppers, with a vertical groove, affording communication between the contents of the bottle and the outside air, thus preventing bursting. The water of condensation which collects makes the closure hermetic. The advantages of the apparatus are that the sterilization of the milk in a current of steam is more thorough and more speedily accomplished than in the water bath, without the danger of spoiling or scorching. The milk retains a degree of freshness of taste not possible when stoppers of rubber and like material are used. [This apparatus is similar in principle to several now on the market in America.—Ed. Reporter.]

Styron in Chronic Purulent Otitis Media.

Dr. Cheltsoff, *Bolnitchnaya Gazeta Botkina*, May 9, 1890, ascribes great value to styron in the treatment of chronic middle-ear disease, which does not yield to the most energetic treatment with other remedies. He made special observations in eight cases and obtained brilliant results.

In one case of otitis media of three years standing, the ear was syringed with a solution as follows:

Styron	℈i
Alcohol	f℥i

One part of the above to twenty parts of water. The purulent discharge and inflammatory condition of the ear disappeared. The patient was cured and discharged from the hospital within twelve days from the beginning of the above treatment.

He had another patient twenty-one years old, with purulent otitis media since childhood; an acute exacerbation with extreme shooting pain in the ear made the patient call for treatment. Syringing with water for several days did absolutely no good. But when twenty parts of the solution of styron to two hundred parts of water were used to syringe the ear with three times a day, the pain,

swelling and tinnitus aurium were relieved within two days. The patient asked for his discharge from the hospital after the fifth day. On the last examination the swelling in the auditory canal was absent, and the middle ear was free from all inflammatory product and had a normal appearance. During the treatment with styron the author tried in the above cases 1-8,000 of bichloride of mercury solution as a substitute; then the purulent discharge appeared the next day in large amount, and disappeared the following day, after the use of styron was resumed.

There are two forms of styron, the crystal and the liquid. Both have the same virtues, the liquid being the least expensive.

Dr. Cheltsoff used an alcoholic solution, and, in order to ascertain that it was not the alcohol that was so beneficial in the purulent cases, he syringed the ear with alcohol during treatment, which was followed by increased discharge from the ear. The styron used after it, however, made the pus disappear permanently. The author states that when there was much pain it was immediately relieved by styron, and that the latter was an excellent analgesic in all his cases. At present styron is a favorite remedy in the hospital for all obstinate purulent conditions.

Sulphaminol as an Antiseptic.

According to the *Journal de Médecine*, September 7, 1890, sulphaminol, or thio-oxydiphenylamine, is prepared by exposing the salts of oxydiphenylamine, dissolved in water, to the influence of sulphur. The product thus obtained is a light yellow powder, odorless and tasteless, which dissolves easily in alkaline solutions, and more easily in solutions of alkaline carbonates. Alcohol and acetic acid also dissolve it. Solutions of it have a light yellow color. Sulphaminol becomes brown and deep colored at about 311° Fahr.

In contact with the juices of the body sulphaminol separates into its two components, sulphur and phenol. Each of these two bodies having great antiseptic power, it follows that sulphaminol is used in medicine principally as a substitute for iodoform, without possessing the disadvantages of the latter. In the urine it appears as oxydiphenylamine. R. Kobert, of Dorpat, has subjected sulphaminol to experiment, and has proved its perfect harmlessness. Dogs tolerate as much as nine decigrams (fourteen grains) of the drug administered subcutaneously, per kilogramme of body weight. No symptoms of poisoning or of suppuration were observed when this dose was given, and even the appetite of the animals was unaffected. Sulphaminol has no toxic effects on man.

Moritz Schmidt, of Frankfort on the Main, reports successful results with it in laryngological practice. He has employed the preparation especially in suppurations of the maxillary sinus. The strong odor of these suppurations, he says, is dissipated easily only by iodoform and sulphaminol; and as the latter is entirely odorless, it is altogether preferable to the former.

New York Pasteur Institute.

Dr. Paul Gibier, in a circular which seems to have been sent out to the newspapers as well as to medical journals, gives the following as the results of the preventive inoculations against hydrophobia performed at the New York Pasteur Institute since its opening, February 18, 1890.

To October 15, 610 persons, having been bitten by dogs or cats, came to be treated.

In regard to 480 of these persons it was demonstrated that the animals which attacked them were not mad. Consequently the patients were sent back after having had their wounds attended, during the proper length of time, when it was necessary.

In 130 cases the anti-hydrophobic treatment was applied, it having been assumed after veterinary examination or inoculation in the laboratory that the animals which inflicted bites were rabid.

The persons treated were:

64	from New York.	1	from Maryland.
12	" New Jersey.	1	" Maine.
12	" Massachusetts.	1	" Kentucky.
8	" Connecticut.	1	" Ohio.
9	" Illinois.	1	" Arizona.
3	" Missouri.	1	" Iowa.
3	" North Carolina.	1	" Nebraska.
3	" Pennsylvania.	1	" Arkansas.
2	" New Hampshire.	1	" Louisiana.
2	" Georgia.	1	" Ontario, Can.
2	" Texas.		

[This is not exactly the kind of information we desire for the readers of the REPORTER; but as the circular was obviously prepared to impress the laity with the skill of Gibier and the beneficence of his New York Pasteur Institute, it could hardly be expected to have great scientific value.—ED. REPORTER.]

The Grippe as a Cause of Abortion and Miscarriage.

In the Moscow *Meditzinskoïe Obozreniïe*, No. 2, 1890, p. 149, Professor Ivan M. Lvoff, the distinguished obstetrician and gynecologist of Kazan, published a valuable paper on the subject, embodying a set of his own observations which are fully in accord with those recorded by Drs. W. H. Banks, of Mifflintown, and Clarence King, of Machias, in the REPORTER, 1890, April 26, p. 489, and June 21, p. 720. During the last pandemic the author happened to come across ten cases of influenza in pregnant women, all of them being multiparæ; of the number, two were in the first half of pregnancy, and both aborted. One of them was seized with grippe while in the third month of pregnancy, abortion occurring on the seventh day of the disease. The other, a generally healthy woman of thirty-three, ceased to menstruate on October 7, and fell ill with severe influenza on November 20. On November 28 (second day of convalescence), there appeared an incessant sanguinolent vaginal discharge; on December 11, an eight or nine weeks ovum was expelled. The remaining eight women were in the second half of pregnancy. In two of the cases, referring to patients in the seventh and eighth month of pregnancy, miscarriage followed—in one on the fourth day of the attack; in the other on the fifth. The infants were born alive, but very weak; and they survived only a short while. Macroscopically their placentæ appeared to be normal. In all the four cases of a premature termination of pregnancy, the complicating disease was of a very severe type, being accompanied with a high fever, reaching its maximum on the third, fourth or fifth day of the attack. In the other six cases the affection was relatively mild, the temperature attaining its highest stand in the course of the first twenty-four hours of the disease. In one of the abortion cases (that occurring during convalescence) the ovum was subjected to a careful macroscopical and microscopical examination which revealed hemorrhagic decidual endometritis, and an advanced fatty degeneration of the fetal membranes, the epithelium of the villi being especially affected. On the whole, Professor Lvoff comes to the conclusion that severe febrile grippe shows the same unfavorable influence on the course of pregnancy as that produced by typhoid fever.

The Preservation of Milk.

After considering various popular means for the preservation of milk, Dr. Lazarus, in an article in the *Zeitschrift für Hygiene*, viii, 2, 1890, of which an abstract is published in the *Deutsche Medizinal-Zeitung*, Sept. 25, 1890, says that all the ordinary preservatives are to be regarded with distrust. In domestic use only salicylic acid is to be commended, and this only when better means are wanting. For the ready recognition of substances added to milk to preserve it: (a) a specimen is heated for an hour or two; a brownish-red coloration indicates the presence of an alkali, such as soda, sodium bicarbonate, borax or lime; (b) a violet coloration upon the addition of a few drops of a dilute solution of iron chloride is indicative of the presence of salicylic acid.

Dr. Laville's Liquor and Pills.

The investigations of the Berlin police authorities show that Dr. Laville's gout liquor, as made by Bernard, is composed of Spanish wine colored with tincture of cochineal, and containing colchicine and quinine. The gout pills contained silicate and carbonate of sodium, extract of alkekengi and a vegetable powder.—*Druggists' Circular*, October, 1890.

Pasteur Institute.

The *Bulletin Médical*, October 12, 1890, reports that in September 158 persons had been treated at the Pasteur Institute in Paris; of whom 49 had been bitten by dogs the rabid condition of which was proved "experimentally," 93 were bitten by animals recognized as rabid by a veterinarian, 16 by animals suspected of being rabid. The animals that did the biting were, dogs 141 times, cats 17 times.

Aletris as a Cathartic.

Aletris farinosa belongs to the family of the Hæmodoraceæ conostyleæ. Its rhizome is administered in the form of a powder, in doses of nine grains, as a simple bitter tonic. In larger doses it seems to possess cathartic, emetic, and even narcotic properties. Good results have been obtained in colic, dropsy, and chronic rheumatism by its administration.—*Journal de Médicine*, September 7, 1890.

Johns Hopkins Hospital and Women Students.

It is reported from Baltimore, October 28, that Mrs. Davis, Miss Mary Garrett, and their associates of the Committee of Ladies, who resolved to raise $100,000, and give it to the Johns Hopkins University for the purpose of founding a medical college into which women would be admitted, have accomplished their resolve. Mrs. Davis has sent the following letter to the Trustees:

"The committees formed for the purpose of raising a fund to procure the most advanced medical education for women can now place at your disposal the sum of $100,000 for the use of your medical school if you will, by resolution, agree that women, whose previous training has been equivalent to your preliminary medical course, shall be admitted to the school, when it shall open, upon the same terms which may be prescribed for men.

"There is little doubt that a sufficient number of women ought to be educated and trained in such manner as to be fully able to care for sick women who may wish or ought to be treated by women. We have devoted ourselves to the furtherance of this object. We have reason to hope that a university which proposes to found a medical school intended to teach advanced methods in the treatment of those diseases which afflict mankind will not refuse to woman the opportunity of learning such methods. There is now a general interest in our movement. In order that this interest may be sustained, we ask you to consider our offer at the earliest possible moment."

The American Academy of Medicine.

The American Academy of Medicine will hold its next annual meeting at Philadelphia, December 3 and 4.

NEWS.

—Dr. Charles Meigs Wilson has resigned as physician to the Lying-in Charity in Philadelphia.

—Jane Martin, who died in the county hospital in Lancester, Pa., on Saturday night, is said to have been 102 years of age.

—Dr. Charles B. Penrose was elected, on October 28, to fill the vacancy in the surgical staff of the German Hospital in Philadelphia, caused by the resignation of Dr. Ferdinand H. Gross.

—A case of leprosy has been discovered at Chester, Pa., by Dr. J. Frank Evans, the diagnosis being confirmed by Drs. Daland, Pepper and Duhring, of Philadelphia. The patient has been isolated.

—On October 28, Dr. John B. Deaver at St. Agnes's Hospital, opened the neck of a woman suffering with cancer of the œsophagus, with a view to its removal, if possible. As infiltration prevented this, he did a gastrotomy.

—It was reported on October 29 that a man and his wife and four children, at Middleton, Wisconsin, had been afflicted with diphtheria, said to have been communicated by a stray cat. Three of the children had died of the disease.

—It is reported from Berlin, October 31, that two cases of slight consumption in the hospital "La Charité" are declared to have been cured already by Koch's method. The patients are kept in the hospital still to prevent their making disclosures.

—Dr. J. T. Rothrock has recently received notice from the Commissioners of the Paris Universal Exposition, notifying him that he had been awarded a silver medal for his photographs of American trees, as exhibited by the American Forestry Division in the Department of Agriculture.

—Sister Rose Gertrude, the young English woman who created a great sensation by attempting to spend her life among the lepers of Molokai, one of the Sandwich Islands, is now a governess in the family of the Superintendent of the Inter-Island Steam Navigation Company at Honolulu. There is said to have been no truth in the statement that she was engaged to Dr. Lutz, about whom and Sister Rose there was so much talk.

MARRIED.

Vissel — Weidemeyer. — On October 2, 1890, at the residence of Dr. S. S. Brumbaugh, at Pipersville, Pa., by Rev. T. C. Strock, Dr. Julius T. Vissel, of Baker Summit, Blair Co., to Miss Mary Weidemeyer, of Pipersville, Pa.

Nash—Duckworth.—At Erwinna, Pa., on on October 8, 1890, by Rev. T. C. Strock, Dr. A. B. Nash to Mrs. Eliza Duckworth, both of Frenchtown, N. J.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

ORDER IN TIME

The Pocket Record and Visiting List for 1891

Is now in preparation. Will be ready December 1st.

TWO SIZES:

1. For 30 Patients a week (with or without dates), . . . $1 25
2. For 60 Patients a week (without dates), ... 1 50

☞ *To paid-up subscribers to the Reporter a reduction of 25 cents will be made from these prices.* **Send Money with Order.**

Clinical Lecture.

STOMATITIS.—DIARRHŒA IN INFANTS.[1]

BY H. A. HARE, M. D.,

CLINICAL PROFESSOR OF DISEASES OF CHILDREN, UNIVERSITY OF PENNSYLVANIA, ETC., ETC.

Stomatitis.

Gentlemen: The first case I show you today illustrates a disease which is frequently seen in children, but generally in those not so far advanced in age as is this boy. It is a case of ulcerative stomatitis, so called. Stomatitis is a very important disease, affecting, as it does, at one period of life, almost every child, producing at times very serious systemic disturbances, and occasioning considerable anxiety on the part of the parents. It may also at times produce reflex nervous trouble, such as a slight spasm. This affection has been divided into different classes by various authors, all of whom appear to confound more or less the various forms.

Catarrhal Stomatitis.

According to the best authorities, the simplest form of stomatitis is the catarrhal form. This amounts to nothing more than a simple hyperemia of the entire mucous membrane of the mouth, which may extend to that of the pharynx, and perhaps down the œsophagus, or at times even through the entire alimentary canal. It corresponds to an acute cold in the head, so far as the pathological changes in the mucous membrane are concerned. Under these circumstances we are generally called to see the child because it has stopped nursing, or, if it be older, because it complains of a sensation of heat in the mouth, attended with a great deal of slobbering, and associated with crying and a constant moving of the hand to the mouth. Occasionally there is a slight febrile movement. Upon placing the finger in the mouth it is found to be hot to the touch and inflamed. This is probably due to the fact that there is an increased hyperemia, and consequently an increased local temperature. This is the simplest and mildest form of the disease. A little care devoted to the cleansing of the nipple, or regulating the diet, together with the use of some febrifuge mixture, such as the citrate of potassium and water, will relieve the child in a few hours, unless the attack be so severe as to bring on the aphthous form, or the mild ulcerative form.

Aphthous Stomatitis.

Aphthous stomatitis is really in one sense an ulcerative stomatitis, and yet it is not called so in the text-books. It is a stomatitis in which the catarrhal process has been so severe, particularly about the mucous follicles, that it has resulted in the death in small spots of the epithelium of the tongue and buccal mucous membrane. Small, superficial ulcerations are formed, without any induration around their bases, and are not excavated—a form, practically, of a very mild ulcerative stomatitis. Aphthous stomatitis has been confounded by many writers with thrush. When a child comes to you with white, raised spots upon the tongue, that is thrush; if, instead, there are simple ulcerations upon the tongue, that is aphtha. In aphthous stomatitis, or "baby's sore mouth," as it is frequently called, the child loses its appetite, has a high fever, sooner or later develops diarrhœa or obstinate constipation, and may present severe nervous symptoms, twitchings of the muscles, and turning in of the thumbs. This condition requires careful treatment. It should be

[1] Delivered at the University Hospital.

watched closely. A mixture may be prescribed containing:

℞ Potass. chlorat. . . . . ℥ss–i
Tinct. myrrhæ . . . . . gtt. v–x
Elixir. calisayæ . . . . . f℥iii

M. S. One teaspoonful every three or four hours.

As a rule children do not object to this mixture, since it is agreeable to the taste. Why do I give this? Because the chlorate of potassium is eliminated chiefly by the salivary glands, thereby bathing the mucous membranes with medicated saliva, and it is practically impossible to make a local application to the sore spots in young children. As a rule, marked relief speedily follows the use of such a prescription. One contra-indication only exists, and that is any acute renal inflammation, which, however, is a rare condition in childhood, unless it follows an acute disease. In such cases we must resort to other treatment, or use the chlorate in very small doses.

Ulcerative Stomatitis.

We now come to what is known as the true ulcerative stomatitis; and this is a disease which in severity greatly surpasses aphthous stomatitis. It is accompanied by the formation of pocketed ulcerations over the mucous membrane of the mouth, depressed, serpiginous, with crater-like edges and yellow bases, surrounded by induration, and often confluent, spreading over the lips and even down upon the chin in bad cases. There is a constant dribbling of saliva in all forms, wetting the skin of the chest. This is frequently followed by an eruption of eczema over the chest and abdomen. The nasal mucous membrane becomes involved in the process, and the nostrils are stopped up, resulting in breathing through the mouth. This causes the tongue to become as dry and scaly as it does in typhoid fever. Here the local treatment is identical with that in the other varieties. If the child is old enough, the ulcerations should be touched up with the stick of silver nitrate or a strong solution of the same salt. The stronger solutions hurt less than do the weak, and a solution containing from twenty to thirty grains to the ounce is the best for this purpose. It should be applied with a camel's hair brush, care being taken that the brush is not dripping wet. All that is necessary is to moisten the surface of the ulcers. At times a little cocaine may be used, but generally the burning of the cocaine is worse than that of the silver, and we thus use two medications instead of one. Fever mixtures of various kinds are wanted. Particular attention should be paid to the bowels and kidneys. The urine is always found to be concentrated, and it is not only well to use the chlorate of potassium solution already named, but it is also wise to order Vichy or some other mineral water, which will act upon the liver and at the same time wash out of the kidneys the potassium products and lower the specific gravity of the urine.

Noma—Cancrum Oris.

We now advance to another form of ulceration of the mouth, known as cancrum oris or noma, which is practically not a stomatitis. We might say that this is an invariably fatal condition. Perforating ulcers appear upon the mucous membrane, going on to gangrene, causing sloughing away of the cheeks, so that the inferior maxilla is exposed. It is accompanied by great loss of flesh, wasting, high fever, cachexia and rapid death. It is a very rare condition in this country, and is probably due to some micro-organism not yet identified. We may use a supporting treatment and apply silver nitrate and other caustics locally; but death usually follows.

This boy has the ordinary mild stomatitis, a little too severe for aphtha, and too mild for the ulcerative form. In some cases of the aphthous and milder ulcerative varieties, and always in the severe forms, the systemic depression that is produced is simply appalling. Within twenty-four hours the child will sink into a complete collapse. Many English writers consequently believe that alcohol should always be used in these cases; and this is a matter it will be well to bear in mind.

You will find among nurses, and particularly monthly nurses, that they always assert that this disease is bound to "go through" the child. Practically this is so. I hardly ever see a case of stomatitis which is not followed by a catarrh of the bowels and stomach, and the patient is usually ill at least ten days. In such cases, as soon as the diarrhœa becomes excessive, some astringent mixture may be given. But do not check such a diarrhœa too rapidly, or serious consequences may follow, and even convulsions in young infants. Paregoric or aromatic sulphuric acid are best for this purpose, their

use being stopped as soon as the stools are reduced to two or three in the day.

Thrush.

I have passed over the condition known as thrush, which is often incorrectly called "baby's sore mouth." Thrush is an entirely different disease, due to the presence in the mouth of saccharomyces albicans. It is due to a fungus and differs from aphthous stomatitis in the fact that it grows from the surface like tufts of mould. Its size varies from that of a pin's head to that of a small finger nail. Thrush is found upon the tip and edges of the tongue as a rule. Practically it presents the same symptoms as does stomatitis: a hot mouth, dribbling, inability to take food on account of the severe pain, although the child is intensely hungry. This is one reason why collapse is so frequent in stomatitis. If the child is old enough to take a mouth-wash, give it a mild carbolized solution, say a one per cent. solution of the crystallized carbolic acid, washing the mouth every two or three hours. The chlorate of potassium is not as useful here as in stomatitis. The carbolic acid is more of an antiseptic and hence is more serviceable. Thrush rarely extends down through the alimentary canal. Some clinical authorities say they have found the fungus in the stomach and even in the small intestines; but this is very rare.

The boy I showed you with the ulcerations around the edge of each tooth has a condition somewhat different from the ordinary stomatitis, in the fact that the ulceration has extended to the gums. It is comparatively rare for this to occur. I do not know what he received from the dispensary. He came in on Saturday for the first time, and is better since using his mouth-wash. An excellent remedy to use as a wash is the sulpho-carbolate of sodium, five to ten grains to the ounce. This is perfectly innocuous, thus having an advantage over carbolic acid.

One word as to the diet in these cases. Parents always want to know about the diet. This is a very important matter. We cannot cure our patients unless it is attended to. Do not give anything which contains sugar. Cut down the sweetening of the bottle, or use instead a small amount of saccharine. For an older child, order broths, thin, non-greasy soups, and largely a milk diet, washing out the mouth with an antiseptic wash after each meal.

Serous Diarrhœa.

The baby I now show you is three months old, and has had a watery diarrhœa for the past two weeks attended with but little pain, the child crying only occasionally. This is generally the case with a watery diarrhœa. In mucous diarrhœa we nearly always have tenesmus and pain. The child has been fed upon condensed milk, one part to sixteen of water ever since its birth until last Saturday, when it was ordered cow's milk. Undoubtedly this attack the child is suffering from is due to the use of improper food. It was getting condensed milk instead of human or cow's milk. This is one class of cases in which we are apt to meet with thrush.

Mucous Diarrhœa.

The first case you see of mucous diarrhœa in children will puzzle you. It must be controlled; but how can this be done. The first thing is to remove the cause, and then to cure the condition produced by the cause. The mother now tells me that the baby has some green in its stools. This does not generally occur in serous diarrhœa. The presence of green usually indicates a mucous and not a serous diarrhœa. These green spinach stools of young children are always due to fermentation, and we rarely have fermentation when we have a serous diarrhœa. A small indigestible particle of food lying in the intestinal canal produces an irritation of the mucous membrane and consequent depression of vitality. A gradually spreading catarrh is produced with a mucous secretion, thick and tenacious, which coats the particles of food. These are then rolled along in the canal until finally the child has in its alimentary canal a decomposing piece of milk or meat covered with mucus which cannot be digested. Active inflammation is set up, and fermentation follows, accompanied with the growth of a fungus. These passages are nearly always acid, instead of being alkaline. Should you give the child an astringent mixture now, you will do it harm. Nature is trying to relieve the child by washing the irritating substance out. Something must be given to clear out the alimentary canal. The best thing is a dose of castor oil, a soothing purge taking five hours to act and facilitating the discharge of the immense amount of mucus thrown out in the alimentary canal. Then administer the astringent mixture. If the child has a puffy

distended belly, indicating a chronic condition, follow the purge with tonics and alkalies. A mixture of bicarbonate of sodium and gentian is the best remedy for such cases. This primary purgative treatment will occasionally be objected to by the parents, and then it must be explained. If we are compelled to give an astringent, one of the best for a young baby is chalk mixture. This, however, is hard to swallow, and it may be better to give one half or one drop of aromatic sulphuric acid to a child of six months or one year, combined with syrup of ginger, elixir curaçoa, or other adjuvant, to render it palatable. A mixture of bicarbonate of soda, forty-eight grains to a drachm, in six ounces of compound infusion of gentian is an excellent preparation, given in dessert-spoonful doses. If the compound tincture of gentian is used, the dose must be less. The only objection to this is its bitter taste; but this may be overcome by administering a peppermint cream drop before and after giving the dose. The condition of acidity of the alimentary canal is overcome by the alkali, while the compound tincture of gentian is a tonic, overcoming the depression which results from the primary irritation and inflammation.

COMMUNICATIONS.

GUNSHOT WOUND OF THE ABDOMEN.

BY ARTHUR E. SPOHN, M. D.,

CORPUS CHRISTI, TEXAS.

In time of peace gunshot wounds of the abdomen are comparatively rare, especially those inflicted by large missles, which are seldom seen except on the frontier, where the old-fashioned Colt six-shooter is to be found. It was with one of these 45-caliber old timers that the following wound was made.

At 10 o'clock on the morning of June 25, 1889, Adrian Bocanegra, a healthy young man twenty years old, was playing with a pistol, which was accidentally discharged while the barrel rested against his abdomen. The nature of such an injury may easily be imagined; the ball entered about two inches to the left of and a little above the navel, passed through the abdominal cavity and lodged under the skin about one inch to the left of the spine near the tenth dorsal vertebra. The man fell backwards and then got up and walked across the street. In about half an hour he commenced vomiting blood. There was no hemorrhage from the wound, externally. I did not see him until about 12 o'clock. He was then lying on his back, pallid, with very feeble and frequent pulse, evidently suffering from profuse internal hemorrhage. Air passed occasionally from the abdominal wound, and there was a crackling emphysematous sound, showing that gas had escaped into the loose tissues. There was neither ingested matter nor blood escaping from the wound. I gave half a grain of morphia hypodermically, and made arrangements to open the abdominal cavity immediately.

Dr. Jones, of this city, and Dr. Cock, of San Marcus, assisted in the operation. I sterilized about 10 gallons of water by boiling, and to a part of this I added ten per cent. of carbolic acid, for the hands and instruments; to the remainder five per cent. of boric acid, for flooding the abdominal cavity. I washed the surface of the abdomen with a ten per cent. solution of carbolic acid, shaved off all its hair, and dusted it with powdered boric acid. It was two o'clock when Dr. Jones commenced administering the chloroform. I made an incision through the linea alba, from the navel to about two inches above the pubes, arresting all hemorrhage with hot water, and ligatures where necessary. The peritoneal cavity contained clots of blood, and ingested matter; gas also escaped from the intestines. The hemorrhage, which had been very profuse, had evidently ceased, but recommenced when I began to examine the intestines, one point bleeding very freely—where the ball had passed through the transverse mesocolon very near the bowel, and cut off quite a large vessel, which I ligated. While examining the intestines I kept the cavity well flooded with the boric acid solution, at a temperature of from 100° to 112°. I found four wounds in the intestines, one in the transverse portion of the duodenum, and three in the small intestines, eight openings in all; besides these the mesentery was cut in several places, and contained between the folds several large clots of blood, which I pressed out, ligating the bleeding points when necessary. After persistently flooding the cavity and searching for bleeding points, the water was still very bloody, so much so that I feared there

was some bleeding point that I had not detected. I now enlarged the opening by carrying the incision about two inches above the navel, and again carefully examined for hemorrhage. Upon passing my hand into the cavity of the pelvis, I found it filled with clotted blood, which I removed by flooding the cavity and gently paddling with my hand.

I next turned my attention to closing the openings in the intestines, using ordinary sewing needles, and a fine ligature known as "West India Islands grass line," which I described in the MEDICAL AND SURGICAL REPORTER, August 20, 1887, page 270—a line made, I believe, from raw silk—composed of three separate threads twisted together, which I separated, using one of the fine threads for ligatures, as they are very strong and durable. The first wound closed was the one from which there was so much hemorrhage, in the transverse mesocolon. The ball had passed very near the bowel, which was contused for some distance, and I believe would eventually have given way. I treated the wounded part as if an opening existed, closed the opening in the mesentery—inserting reinforced stitches near the intestine, and also stitched the bowel on each side, keeping well outside of the contused portion, which was pressed into the canal. I used the Lembert suture, which I think gives better satisfaction than any other in such cases. The openings in the intestines were large and ragged, one being almost completely severed. I did not pare the edges of the wound, for I think it a mistake to do this, because it takes time, may produce hemorrhage, and removes the ragged surface, which naturally falls together, interlacing, as it were, and assists in keeping the opening well closed. I inserted the stitches lengthwise of the bowel, a procedure which may shorten the intestine, but does not decrease its caliber, which I consider an important point in closing intestinal wounds. The intestines, being held by the mesenteries, like an open fan, have a tendency to drop together, and if shortened by resection or the closure of a wound, there is little or no strain on the stitches, while the caliber of the bowel is not diminished. On the other hand, if the stitches are inserted crosswise of the intestine, not only will the caliber be diminished, but there will also be a strain on the part. Shortening the intestine by doubling it over has a tendency to strengthen it. I placed the stitches about one-fifth of an inch apart, sometimes closer, inserting extra stitches where the parts did not appear to be effectively closed. All the stitches of a given opening were inserted before any were tied. After closing all the wounds—that is nine of the intestines, and three in mesenteries—I flooded the cavity very freely by pouring the water in from a pitcher, and then raising the side of the table to let it run out, continuing until the water came out clear, at the same time examining carefully for clots or ingested matter. I then wiped the cavity out very carefully with soft sponges, passing them deep into the pelvis, until all fluids had been removed, then closed the abdominal incision, using the grass line, full strength, placed one inch apart, including the peritoneum; between these and to close any gaping points, I inserted specially prepared horsehair sutures, which I find excellent for fine work. The horsehair is prepared by being washed with soap and water, soaked for forty-eight hours in a ten per cent. solution of carbolic acid, and then placed in a glass tube filled with a fifty per cent. solution of boro-glyceride, and securely corked. The hair thus prepared is very elastic and quite strong.

I did not insert a drainage-tube, and do not think they are necessary, when the abdominal toilet is nicely perfected, and there is no hemorrhage. I covered the abdominal incision with boric acid, then a narrow strip of borated cotton, passing a few strips of rubber adhesive plaster across, to give additional support, dusted boric acid very freely over the whole surface, and covered all with a pad of borated cotton, which, with a light bandage, completed the dressing.

The opening where the ball entered was very much torn and powder burnt, and I simply covered it with boric acid and borated cotton. I did not remove the bullet, not wishing to make any more openings into the cavity, but removed it several days after.

It was two and a half hours from the commencement of the operation to the completion of the dressing. My patient rallied well and made a very quick recovery, without any complications. The following is selected from the notes taken daily at the bedside:

Morphia was used to procure rest of the bowel; the urine was drawn with a catheter; mucilaginous drinks and beef peptonoids

were administered, and by the third day a little milk with a little coffee, and the next day some chicken broth. The sixth day an enema of glycerine and milk, of each two ounces, brought about an action of the bowels containing considerable fecal matter.

On July 4 I dressed the abdominal wound for the first time. I found the dressings dry, just a little soiled along the line of the incision. The wound was completely healed. I removed all the stitches and washed the abdomen with a five per cent. solution of carbolic acid, using sterilized water, applied a few strips of adhesive plaster dusted with boric acid, and replaced the pad of borated cotton and the bandage. The patient's pulse was 72, his respiration was 20, his temperature 99½° and he was feeling quite comfortable.

July 9 I removed the bullet from his back, which was not causing any inconvenience, the slight incision soon healing. Of course, while I now considered my patient quite well, I kept him under observation, allowing but little exercise and a very restricted diet. It is now three months since the operation, and he enjoys his usual health and is able to do a hard day's work.

I have given a very full report of the above case because it is one of great importance, not only from its gravity, but because it may assist my professional brethren of the rural districts in coming to a conclusion as to what course to pursue in cases of gunshot wounds of the abdomen and their proper management. That they need not allow the unfortunate sufferer to die, because there is no specialist at hand, I have always believed; and I maintain that one man can do just as much as another, if he only thinks so; that surgery, after all, is only a question of anatomy and good judgment. When I made my first abdominal section I had to ride fifty miles on horseback, give chloroform, and operate alone for obstruction of the bowels—and the operation was successful.

In looking back over the above case, I see no change I would desire to make, the treatment being the same that I follow in all cases of abdominal section; and my success has been all I could have desired. There are a few details I consider of great importance, viz.: a well-ventilated room kept at a temperature of from 98° to 100° F., during all capital operations; plenty of sterilized water, and the utmost cleanliness in operator and assistants. I always take a bath and change my clothing just before all serious operations and require the same, if possible, of all assistants—at least their hands must be thoroughly disinfected, using a strong solution of carbolic acid. In dressing all wounds I use a large quantity of boric acid, enough to absorb any moisture. In abdominal sections I scarcely ever examine the wound before the fifth day, and do not change the dressings until the ninth or tenth day, when I remove the stitches. I adopt the same course in amputations.

I would not rely on the hydrogen-gas test, because a bullet may pass in close proximity to the intestine, cutting partly through it, which will be followed by perforation and certain death. No surgeon would, in my opinion, be justified in treating a penetrating wound of the abdomen, who did not immediately make an exploratory incision, in order to arrest hemorrhage, repair any injury to the intestines and cleanse the cavity. On October 2, 1890, I chanced to be traveling on the cars from Corpus Christi to San Diego, Texas. At one point we stopped to take on wood, and I left the car for a little walk along the track and found a man lying on the ground, supposed to be dying. Upon examination, I found he had been shot—the ball passing through the abdominal cavity, entering about three inches to the left of and a little below the navel, passing out a little to the right of the spine. I had not time to operate where he was, so I put him in the baggage car, and at the next station opened the cavity. There was nothing to indicate that the intestines were injured. It was now eight hours since he was shot, there was no emphysematous sound, no air or blood escaping from the wound; the only thing showing severe injury was his weak and quick pulse and collapsed condition. There was considerable blood in the cavity, the ball having penetrated the descending colon and cut a small artery in the mesentery. The blood in the cavity was evidently from this artery, which I ligated at once. The wound in the intestine was large and very peculiar, the mucous coat being turned out, completely stopping up the openings. I closed the openings—using Lembert's sutures—washed out the cavity, stitched it up and used the ordinary dressing after laparotomy, and left the man with his friends, giving instructions, which I suppose were not followed.

On the fifth day after, he sent to ask me

if he could have something to eat. I was told he felt well, and had little or no fever, and so I allowed him a very little liquid food. I have since heard that he died, and that he had paralysis of the lower extremities. I have no doubt but that the ball injured the cord and probably fractured one of the vertebra. The fact is I had no one to assist me except ordinary passengers, and one of them fainted just as I opened the abdominal cavity; so that I had no time to examine as to the course of the ball. Even under the circumstances, had the ball not injured the cord I am satisfied this man would have recovered. He had no surgical attendance, but lay in a little Mexican hut.

This case simply illustrates the fact that we may often save lives by acting promptly and fearlessly. I frequently see notices in our State papers saying: "Shot through the bowels; died a few hours after;" and I find invariably that no attempt was made to save the unfortunate, or at least to give him a chance for life. I live in a rural district myself, or rather in a little country town, so that I know how one feels to stand by and see the life of a fellow-man slowly ebbing away; and if this report will stimulate my fellow-practitioners of the rural districts to do their duty under all circumstances, I am more than repaid for my trouble in making it.

THE TORSION OF ARTERIES FOR THE ARREST OF HEMORRHAGE.[1]

BY J. B. MURDOCH, M. D.,

PITTSBURGH, PA.

There is no subject of greater interest to the practical surgeon than the arrest of hemorrhage. This remark is equally true whether the hemorrhage comes from a wound accidentally inflicted, or one made intentionally, by the surgeon's knife. Without the means of stopping the flow of blood from bleeding vessels, the surgeon's art would be greatly crippled, and surgical operations, where blood-vessels must be divided, would be impossible.

There is no sight so appalling as a formidable hemorrhage. When a large artery is opened, the blood gushes out in an angry stream, the face becomes pale, the color leaves the lips, the respiration becomes sighing, the heart fails to beat, and death closes the scene. Without any knowledge of the circulation or nature of the blood, or of the means by which its flow from a wound could be arrested, what a terrible and mysterious sight it must have been to the early races of men to see one of their number perish from hemorrhage. What, for instance, must have been the sensation of our first parent Adam, as he looked upon the wounds of his dead son Abel, with the stain of his blood upon the ground. Surgeons from the earliest ages have shared with the people this dread of hemorrhage, and have ever been striving for the best means for its control. Upon no subject has our profession been more conservative than upon this one—the arrest of arterial hemorrhage. Since the time of Celsus, notwithstanding the numerous methods which have been proposed for this purpose, but two, viz.: the actual cautery and the ligature, have received the endorsement of the profession. But, if the profession has been slow to endorse new methods, its confidence, once gained, has been most unwillingly surrendered. From the time of Archigenes, who practiced in Rome shortly after the time of Celsus, up to the time of Richard Wiseman, Sergeant-Surgeon to King Charles II, the red-hot iron was the sole method employed. Thus, this method of checking hemorrhage after amputation, not two centuries ago, was the same as that used for fifteen hundred years previous. The pertinacity with which surgeons adhered to the use of the actual cautery after Paré's great discovery of the ligature well illustrates the fear in which surgeons stood of hemorrhage. They have used, and seen their fathers use, the red-hot iron, and, notwithstanding the pain it causes and the interference with primary union, they were unwilling to discard the agent which long usage had taught them was successful.

In 1564, Ambrose Paré published his new discovery, which, to use his own language, "was taught him by the special favor of the sacred Deity." In this publication, as is well known, Paré demonstrated the value of the ligature as a hemostatic. But, owing to the extreme fear of hemorrhage, and the criminal neglect of surgeons, it was two hundred years before it was adopted by the profession, and then it came into favor through the influence of Sharpe, one of the surgeons of Guy's Hospital,

[1] Read by invitation at the 16th annual meeting of the Mississippi Valley Medical Association, October 10, 1890.

London, who boldly championed the claims of the ligature to popular confidence. Since this time nothing has dislodged the position which the ligature has held as a hemostatic in the opinion of the profession. The efforts made by Sir James Y. Simpson, of Edinburgh, to substitute acupressure, and the still more recent endeavor of Dr. S. P. Spier, of Brooklyn, to substitute constriction for ligation, have most signally failed. The same statement may be made also in regard to torsion as a means of arresting arterial hemorrhage. It has not received the support of the profession to any great extent; but unlike the other rivals of the ligature, it has had champions for hundreds of years, and still holds a place as a valuable means of arresting hemorrhage, This subject has received but little attention by modern surgeons. The twisting of an artery to arrest bleeding is of ancient origin. It is spoken of by Celsus. A fact often observed that an arm or leg may be torn from the body with the loss of only a few drops of blood, no doubt suggested the method. It has been advocated by such surgeons as Amussat, Dieffenbach, Schroeder, and Syme. But the credit of bringing it prominently before the profession and establishing its efficiency is due to Mr. Bryant, the present distinguished surgeon of Guy's Hospital, London. At this hospital the ligature is seldom used, torsion being chiefly relied upon. Mr. Byrant tells us in the last edition of his *Surgery*, that in two hundred consecutive amputations of the thigh, leg, arm and forearm, all of the arteries were twisted, one hundred and ten of them being the femoral artery; and that in no case was there secondary hemorrhage. Mr. Bryant says: "The physiological arguments in favor of torsion are very great, and the practical advantages seem to be no less. After seven years' experience in its practice, applied to vessels of all sizes, the femoral being the largest, I have had no mishap. I have observed that wounds have united more rapidly and kindly, primary union being the rule. There has been less constitutional disturbance after operation, and consequently less liability to traumatic fever, pyæmia, and other complications, such as we are all too familiar with in the practice of surgery. I have had stumps heal in a week and the patient up in two weeks; without one single drawback, rapid and uninterrupted convalescence following the operation."

Having given this experience of Mr. Bryant, I desire now to give my own as observed at the Western Pennsylvania Hospital, at Pittsburgh. At this hospital, torsion is almost exclusively relied upon to check the hemorrhage from wounded arteries or veins, whether the wound be produced by the surgeon's knife or otherwise. My experience with torsion as a hemostatic, dates back to the year 1872, when I became a member of the Hospital Staff. My colleague had, previous to my connection with the Hospital Staff, been twisting arteries as large as the radial and ulnar. The facility with which this was done, and the fact that the wounds healed kindly and without secondary hemorrhage, induced me to follow their example, at first timidly; but with success came confidence. Having been successful in the amputation of a forearm with no untoward result, I ventured next to twist the brachial after the amputation of an arm; soon after this, the axillary and then the popliteal, and finally the femoral. And now, for the past eighteen years, torsion, for the arrest of hemorrhage after all surgical operations, has been the recognized, and almost the only method resorted to at this hospital. It is to be regretted that records have not been kept of the number of large arteries which have been twisted to arrest the hemorrhage.

The following is a table showing the number of arteries divided in cases of amputation, where torsion has been resorted to for the arrest of hemorrhage at the Western Pennsylvania Hospital:

Femoral	116 times.
Popliteal	18 "
Axillary	18 "
Anterior tibial	317 "
Posterior	317 "
Brachial	81 "
Radial	45 "
Ulnar	45 "

There are two methods by which the torsion may be applied:

1. Limited torsion.
2. Free torsion.

In the first method, two pairs of forceps are required. The first pair grasps the vessel at its cut extremity, and pulls it from the sheath. It is then seized by the second pair at a point from one-half an inch to an inch above the cut extremity of the artery; this second pair being held at right angles to the long axis of the vessel. The first pair is then given three or four sharp turns.

By the second method (free torsion), only one pair of forceps is required. It is the one recommended by Mr. Bryant as not being so likely to injure the external coat of the artery. And this is the method which was adopted in the cases which I have given.

A good pair of forceps is required, which will hold the end of the artery firmly, that has no lateral motion, and with serrations blunt enough to obviate any laceration or cutting of the parts seized by the blades. The vessel should then be drawn out, as in the application of the ligature, and three or four sharp rotations of the forceps should be made. In large arteries, such as the femoral, the rotation should be repeated until the sense of resistance has ceased. The ends should not be twisted off. In small arteries, the number of rotations is of no importance, and their ends may be twisted off or not, as may be preferred. In all of the cases mentioned in the above table torsion of the arteries and veins was the method resorted to to control hemorrhage.

In addition to these cases, of which we have a record, the method of torsion has been the one resorted to in all other surgical operations performed during this period, such as amputations of the breast in women, the removal of tumors, the excision of joints, etc. It is within bounds to say that torsion has been resorted to at this hospital in thousands of cases without any mishap. We have had no case of secondary hemorrhage which could fairly be attributed to the method of controlling the hemorrhage.

The advantages of torsion as compared with ligation are:

1. The greater facility with which it can be applied. I am fully aware that this proposition is disputed, but to those who are familiar with both methods, there can be no doubt that torsion is the easier of the two. For the ligation of an artery, an assistant is required to seize the vessel and draw it out while the ligature is applied. For torsion, the surgeon requires no assistant. The vessel must be seized by the forceps in either case. In torsion, it only requires three or four turns of the forceps to complete the process, which can be accomplished in as many seconds. When a ligature is applied, let the operator be ever so skilful, the thread may break or slip off the vessel, but if neither of these accidents occur, the process cannot be accomplished in anything like the same time.

2. Torsion is a safer method, being less liable to be followed by secondary hemorrhage. This proposition has been absolutely proven by the experience in the use of torsion at Guy's Hospital, London, and I have now given additional proof by the experience given in this paper.

3. Healing is facilitated because the wound is free from any irritating or foreign body. This proposition is so plain that it should not require an argument. It was true before the antiseptic treatment of wounds had come into such general use, but it is doubly so now. The catgut ligature is no doubt a safer ligature than the silk, for it does not require an ulcerative process for its discharge, and when this ligature has been made thoroughly antiseptic, it is no doubt the best. But a ligature rendered thoroughly antiseptic is not always at hand, and those surgeons who have had most experience with the antiseptic treatment of wounds, will, I think, be the first to admit that, in spite of their most careful attention, septic germs are often introduced into the wounds by means of the ligature. Even after every precaution in preparation and preservation, the handling of a ligature in its application is a frequent source of infection. But there are other objections to its use. The catgut ligature may dissolve before the artery has become closed by the natural hemostatic process, or it may unbind. Both of these accidents have been the frequent cause of secondary hemorrhage.

On a recent visit to some of the principal hospitals of New York City, where the operators and assistants possessed the greatest skill, I was not surprised to see that in many instances a ligature broke, and in other cases slipped off the vessels before they were secured. This was to me exceedingly annoying to witness, when I knew that the vessels could have been so easily twisted while they were in the grasp of the forceps. When the question was asked one of these operators, a distinguished surgeon: "Why don't you resort to torsion?" the reply was: "we are afraid to trust it." This answer might have been given with equal force by Richard Wiseman in the 17th century, when asked why he did not resort to the ligature instead of the red-hot iron.

In a matter so important as the arrest of arterial hemorrhage, it is proper that surgeons should be conservative; but there is such a thing as pushing conservatism too far. In the torsion of arteries, I claim we have an improvement upon ligation; its

claims for recognition rest upon physiological arguments, which cannot be shaken, and its reliability as a hemostatic has been proven by abundant experience.

CHRONIC PERIOSTITIS WITH EFFUSION TREATED WITH ASPIRATION AND INJECTION OF EMULSION OF IODOFORM AND GLYCERINE.

BY JOHN B. CRANDALL, M. D.,
STERLING, ILL.

The subject of this communication was a young woman, sixteen years old, living in Clinton, Iowa. My first examination of this patient was in the summer of 1889. She had then an enlargement of the right tibia with tenderness and lameness of the knee after much exercise in walking. After hearing the history of the case I came to the conclusion that there might be a specific complication, and so I put her on the syrup of iodide of iron. She improved for a time, and I lost sight of the case until about May 1, 1890, when she came to Sterling for treatment and remained for two months. The left knee was now swollen, painful at times, and tender upon pressure, with more or less effusion bulging the patella and setting back under the tendon of the quadriceps extensor. I aspirated the knee, and drew off something like one-half a pint of fluid. The fluid was straw-colored, and after standing for twenty-four hours, a portion of it became ropy and albuminous. The accumulation reappeared and in forty-eight hours was as great as upon the first examination. I then aspirated the same as before with the same results. In order to check the effusion I now filled a large hypodermic syringe with an emulsion of iodoform and glycerine, and injected this down over the tender point, which was upon the lower end of the outside of the femur a few lines above the articulation. I then ordered complete rest and had the limb encased in a flannel bandage, to be applied several times a day after saturating in as hot water as the patient could stand with comfort. I also ordered pills containing protiodide of mercury which were given for some weeks. This was followed with the syrup of the iodide of iron, with good results. The patient made a favorable recovery, and is now walking upon the limb, and has had no further effusion about her knee.

It was interesting to note in this case how promptly the tendency to effusion was checked by the injection of the emulsion of iodoform and glycerine. A part of the good result must be attributed of course to the bandaging and the hot water, and perhaps a good deal to the specific medication.

DISLOCATION AT THE OCCIPITO-ATLOID ARTICULATION.

BY E. L. ANNIS, M. D.,
CORONER OF LA PORTE COUNTY, LA PORTE, IND.

The occipito-atloid articulation is one of the strongest found in the human anatomy; it is a double arthrodia, and is held together by seven ligaments. Dislocations are so rare in this region that I may perhaps be pardoned for reporting the following interesting case falling under my observation.

I was called in my official capacity about six P. M., on the thirty-first of May, to hold an inquest over the remains of a man who had just been killed in a saloon in La Porte. On arriving at the place, I found a slender man about five feet four or five inches in height, and weighing about one hundred and twenty-five or one hundred and thirty pounds. I recognized a well-known saloon habitué, and made a superficial examination to discover the cause of his rapid "taking off." There was a bruise over the bridge of the nose and superciliary ridge. The nasal bones were loosened, and a slight flow of blood escaped from the nares. I noticed an unusual mobility in the cervical region, and came to the conclusion that there was an atlo-axoid dislocation. I at once called Dr. R. O. Crandall, of our city, to perform the autopsy, a practitioner of over forty years' experience and well qualified to do the work competently and thoroughly. He proceeded and, after carefully separating the muscles, found a complete backward dislocation of the occipital bone with a rupture and stretching of all the ligaments involved. The finger easily passed between the two bones. His judgment was that the separation was greater on the left side, and that the ligaments were more completely ruptured on that side. The chest was next opened and the heart and lungs were found normal, as were the blood-vessels. The abdomen was next examined. The mucous membrane of the stomach was slightly congested, but otherwise normal, as were the

spleen and pancreas. The kidneys were "hog-backed," but the tissue and pyramids were normal in appearance. On external view no other discoloration, bruise or injury was detected, and the opinion was given that the dislocation above described had produced instant death. I next proceeded to summon the witnesses to the killing, and it was developed that the man had been struck a blow in the face by the clenched fist of a sturdy young farmer from an adjoining township, and at once dropped dead. The assailant was about twenty-three years old, five feet five or six inches tall, and weighed about one hundred and sixty pounds, a strongly-built, muscular man capable of striking a powerful blow. The evidence was strong that he held nothing in his hand. It is but proper to state that he was somewhat under the influence of liquor and the man who suffered the dislocation was quite drunk. This may have been an important factor in the causation of the injury, as the relaxed muscles of one in this condition could offer no resistance to a powerful and suddenly-applied force.

From these facts a verdict was rendered that the man's death was caused by pressure upon the cord, as a result of this occipito-atloid dislocation following the blow in the face. The assailant was recently tried and convicted of manslaughter and sentenced to two years in the penitentiary.

The older writers maintained that this dislocation was impossible from the application of any external force, a fracture of the vertebræ occurring before a dislocation; but it is now thought that any severe, sudden force exerted, either from before, backwards or *vice versa*, may produce it. In the *International Encyclopœdia of Surgery*, five cases are cited caused in various ways, the force being conveyed through the cranium to this articulation. The case above given is well authenticated and its rarity is the only reason I have for publishing a description of it.

Rates on Surgical Chairs.—The Inter-State Commerce Commission has ordered that the present rate on surgical chairs be reduced—if shipped in less than carloads—from double first-class to first-class, or a reduction of about one-half in the rate. This was what the rate was formerly for a long period of time, and until recently, when it was advanced to double first-class, under the analogies of classification.

Hospital Notes.

Harlem Hospital, New York.

Service of Dr. Thomas H. Manley.

Abdominal Injury.

Dr. Manley said that the greater part of the afternoon would be occupied in the consideration of the surgical management of abdominal lesions: traumatic and pathological.

The first case was one of a man 36 years old, suffering with traumatic peritonitis. The patient while in a brawl, the previous Sunday night, was stabbed in the abdomen with a pocket-knife. The blade was driven in its full length, and was then drawn across the abdomen, diagonally to the median line, immediately below the last floating rib, in the right side. The wound was about five inches long. Immediately there was extrusion of the stomach, the transverse colon, omentum and small intestine.

The patient was brought in by the ambulance, one hour after the wound was inflicted. The house surgeon, Dr. Dade, after proper precautions, returned the extruded viscera and closed in the wound, without drainage. Strange to say none of the viscera was wounded. The man did well until the morning of the third day, when tympanites appeared, the pulse beating at 140 per minute, and the temperature being 104°. In fact septic infection had developed. Dr. Manley now re-opened the wound, removing all the sutures, when a large quantity of dark, curdy serum escaped. He said, with his fingers within the peritoneum, he could easily feel the edge of the liver along its lower border, and the bare intestines. The peritoneal cavity was now freely irrigated with warm, sterilized water, the edges of the wound were brought partly together with adhesive straps, and antiseptics were applied.

Hernia.

The next case was one of a young man of thirty, who had a reducible inguinal hernia. The fellow had it but six months as far as he knew, and latterly it gave him such distress that he came in to have an operation done. No truss would completely keep it up. It would slip down on either side of the bulb, in spite of all he could do, and

hence he had to throw the truss aside, and wear a suspensory-bag. Latterly it had attained such size, that a great prominence was visible, under the trousers, and when he assumed an upright posture, he had a most distressing feeling of nausea and retching.

Dr. Manley said that on careful examination in the ward he found the protrusion, probably displaced and hypertrophied omentum; that it was evident though the extruded epiploon could be returned, it was not so with the sac, which he said he knew by its feel was an old one; intimately and rigidly adherent to the spermatic cord. He said that this hernia was, as the vast majority are, of a congenital or pre-natal origin, the testis and cord as they entered the inguinal canal carried with them a particular fold of the peritoneum, the sac; and it was preserved, till late in life, when the parts were put on the strain and the rings so weakened that it allowed the abdominal contents to enter.

Dr. Manley said that he regarded the prognosis here as remarkably good, and that he felt he could, with almost a positive certainty, promise a cure. He would remove the cause, practically, by three steps, viz., 1. Open the sac, drag the slack omentum well out and cut it off. 2. Attack the whole immense indurated sac close to the peritoneal border, and next obliterate the ring. He would depend on adhesive inflammation, internal and external, to fix and retain the viscera at the gap and seal the gaping vent.

The operation was commenced by making a free incision about five inches long, dissecting away the sac and removing an enormous omental mass. Then he sewed the strip of omentum into the widely-separated pillars of the ring.

Laparotomy Avoided.

Dr. Manley next presented a woman who was placed under his care by the patient's family physician for a laparotomy for peritonitis. Dr. Manley said, with the aid of the time-honored mercurial inunction over the abdomen, and morphine internally, the woman had rapidly recovered without the use of the knife and would be discharged in a few days, cured.

(Note.—One week after clinic. The patient with stab wound was doing well, and the hernial case rapidly recovering without any untoward event.)

Periscope

Kraurosis Vulvæ.

Dr. Charles N. Smith, of Toledo, Ohio, says, in the *Buffalo Medical and Surgical Journal*, October, 1890, that Mr. Lawson Tait, in 1887, described, under the name of "Serpiginous Vascular Degeneration," a diseased condition of the nymphæ, which was essentially a progressive atrophy of these parts, attended with the appearance of exquisitely sensitive areas of a brick-red to purplish color upon mucous membrane. These sensitive areas had a tendency to disappear after a time and appear in another situation, or extend in a serpiginous manner. This extension generally continued until the whole inner surface of the labia minora and the vestibule had been traveled over. These spots were so sensitive to pressure that intercourse could not, as a general thing, be tolerated. The disease was one of long duration; little amenable to treatment; recovery generally spontaneous; and resulting in atrophy of the nymphæ and narrowing of the vaginal opening. This condition generally occurred, as observed by Mr. Tait, at or after the climacteric, although he reports one case in a girl of seventeen years.

It is very often, but by no means always, associated with vascular caruncle of the urethra. . . . This affection has been alluded to by Simpson and various other authors, but no description which Mr. Tait has seen includes all the facts that may be observed in connection with it. It is always confined, in his experience, to the mucous membrane on the inner surface of the nymphæ, and is never met with on the labia majora or in the vagina higher than the vestibule.

Dr. Smith says that the disease does extend to the labia majora, although not observed there by Mr. Tait.

As to the course and final termination of this disease, Mr. Tait says it is, in fact, a progressive atrophy of the mucous membrane, the last textures affected being the blood-vessels and nerves; for when the process has been completed, the pain ceases, the redness disappears, and nothing remains but a vestibulum vaginæ so narrow that incredulity may be excused when the patient states that she has given birth to children.

The treatment recommended by Mr. Tait is the application of strong carbolic

acid to the red spots, and the insertion between the labia, at bed-time, of a tampon wet with a suturated solution of neutral acetate of lead in glycerine.

In a recent paper, Dr. H. H. Ohmann-Dumesnil reports thirty-five cases which he has collected from various sources, including three cases observed by himself. Breisky's cases are included, but no reference is made to those seen by Tait. Robert F. Weir first described a case of this disease in March, 1885. In these thirty-five cases the presence of thickened areas or plaques of various colors, red, gray, milky, or pearly or opaline, is mentioned as occurring in nearly all. Atrophy of some part or parts of the vulva was present in all. In some of them the labia majora were affected, which is contrary to the observations of Tait. Pruritus, a condition not mentioned by Tait, was present in fifteen, and ranged in severity from moderate to intense. Of the thirty-five cases, four had suffered from syphillis. Gonorrhea had occurred in two. Leucorrhea, a condition present in all of Tait's cases, is mentioned as being present in eleven cases.

Treatment was generally successful in those cases which were seen in the earlier stages, but was unsuccessful in the atrophic stage. The treatment consisted in curetting the spots, and in the application of liquor ferri sesquichloridi, lotions of salicylic acid, pyrogallic acid and acetic acid.

Dr. Smith describes a case under his care as follows: "Mrs. A., aged fifty-two, married, and the mother of two children, the younger aged sixteen, consulted me in April, 1888. She was of a marked nervous temperament, slight and delicate figure, but apparently in good health. She had never had syphillis nor gonorrhea. Six years before, and four years prior to the cessation of menstruation, she first noticed a pruritus vulva, attended with pain and scalding upon urination. The pruritus gradually increased for about one year, when she consulted a physician, who found and removed a urethral caruncle. Following the operation there was relief from the pain and scalding upon urination, but no abatement of the pruritus. On consulting a second physician, several months later, she was told that her trouble was undoubtedly the result of diabetes. She was therapeutically and dietetically treated for diabetes for nearly a year, and was given carbolized washes and various ointments for the vulva. The carbolized washes somewhat relieved the pruritus, although it was always present in some degree. This physician made no local examination and never examined the urine for sugar, although he was positive in his diagnosis of diabetes."

He says he carefully examined several specimens of her urine, obtained at different times, and found no trace of sugar.

On examination of the vulva a most peculiar condition was found. The hairs on the parts were few, harsh and gray. The vulva was slightly gaping. The labia majora were shrunken, inelastic and composed almost entirely of integument, the subcutaneous tissue having nearly disappeared. A little over one-half of the lower or posterior portions of the labia minora were atrophied, while the upper portions were natural in size and appearance, except for the purple spots mentioned below. The vaginal opening was so narrowed that only the small virgin size of Sim's speculum could be inserted. About one-fourth of an inch below the meatus urinarius was an exquisitely sensitive patch of dark purple color, a little over one-fourth of an inch in width, and extending downward and to the right for about one-half of an inch. Another similar spot, but smaller, was found on the inner or vaginal surface of the upper portion of the left labium minus. Small and exceedingly thin membranous tags were all that remained of the hymen. The clitoris was normal. The integument of the lower portion of the labia minora and on the inner surface of the labia majoria was dry, smooth, shining, and bluish-white in color, with here and there a few small thickened spots of a milky-white color. The spots, and the atrophied areas generally, were not so sensitive to pressure as were the red spots. In fact, the kraurotic changes seemed to have been nearly completed in the lower portion of the vulva, while they were still progressing in the upper portion. The uterus measured over two inches in depth. A slight thin discharge escaped from the os.

Thinking that the pruritus might possibly be caused, or at least aggravated, by the discharge, Dr. Smith inserted into the vagina or had the patient do so, twice a day a dry absorbent cotton tampon to collect the discharge and prevent its escape into the vulva. This was continued for two weeks with no result. Having, by this time, decided that nearly the whole trouble arose from the two purple spots, he applied to

them equal parts of tincture of iodine and carbolic acid. This treatment resulted in a considerable diminution of the pruritus, but did not remove the spots. He then applied pure carbolic acid, which caused excruciating pain, but was, in a short time, followed by complete relief of the pruritus. These applications were continued from time to time, until the spots were entirely destroyed, or at least until they disappeared. Following the disappearance of the spots was a considerable, but not total, relief from the pruritus. Gradually the pruritus grew less and less until it, too, disappeared. In the two years which have elapsed, since the cessation of treatment, there has been no return of the sensitive spots or of the pruritus.

Uses of Exalgine.

Dr. J. S. Holden writes in the *Lancet-British Medical Journal*, September 27, 1890:

I have used exalgine very frequently since reading Professor Fraser's clinical lecture on the subject, and my experience with it inclines me to the opinion that if generally tried exalgine would take a permanent place among our analgesic remedies, and its proper therapeutic dose and range of usefulness would soon be determined. I consider the proper dose to be half a grain, and not to exceed one grain. This is absolutely safe and free from poisonous effects. As a rule the half-grain dose, in suitable cases, will relieve pain for a short time, perhaps half an hour; on its return a second dose will give a longer immunity, though a third or fourth may be required. I seldom prescribe more than four doses, with instructions that when the pain returns the dose is to be immediately repeated. When the pain is very severe commencing with a double dose is more effectual.

If exalgine fails to relieve pain after the administration of two grains, divided in this manner, I think it is best to let it alone and try some other remedy. From the various published accounts of the poisonous effects which have followed four or five-grain doses of exalgine, it is evident that such doses are dangerous. To derive the greatest benefit from the small doses they should be taken on an empty stomach.

As to its range of usefulness, I find that exalgine is generally efficacious as an analgesic in thin, spare persons of nervous temperament and subject to neurotic ailments, while it fails with the robust, plethoric, or phlegmatic, whose functional pains more often proceed from dietetic causes. It is useless in relieving pain due to mechanical or organic lesions; this often accounts for its failure in apparently suitable cases, where the cause of the pain is obscure.

The first case in which I administered exalgine was that of a young lady with abscess of the antrum, which was lanced; she had three days of pain and sleeplessness, only partially lulled by morphine. One-grain dose of exalgine removed the pain and gave her four hours' refreshing sleep. Nor did she require to repeat the dose. About the same time a delicate, deformed gentleman, whom I was attending for epistaxis, fell off his chair and bruised his sternum against a fender; several hours afterwards he was seized with acute pain in the affected part; this was quite arrested by four half-grain doses of exalgine.

These successes encouraged me to use it in all forms of pain with the following general results: During the late epidemic of influenza it invariably more or less alleviated the frontal and orbital pains which were so marked a symptom of that peculiar disease. In most cases of facial neuralgia and of toothache, not due to caries, it was successful, so much so that some lady patients are loud in its praise. In gastralgia it is uncertain, though a few cases experienced great relief from pain; one of these was recovering from ulcer of the stomach and was much benefited by the half-grain dose four times a day. It certainly gives relief in functional cardiac pain and in attacks of imperfect angina. I have not found it at all successful in allaying the pains of lumbago or sciatica in the cases I have tried it.

It is not to be expected that exalgine will do more than give temporary immunity to painful neurotic affections, which is all that other analgesics confer. It has, however, the advantage, when given in small doses, of being perfectly safe and free from those inconveniences which accompany the administering of narcotics, and which have nothing to do with the relief of pain.

Surgical Treatment of Epilepsy.

In deciding as to the effect of surgical treatment in this malady, a distinction must be drawn between relief and cure, and the circumstances that any operative procedure

attended by severe shock may materially modify the severity of symptoms, has undoubtedly been an important factor in producing reported cures; cures which, if the subsequent course of the case had been observed, would have been found to exhibit only a temporary amelioration of symptoms. Probably every one is familiar with such cases. If the success of operative procedure is calculated from statistics gathered from journal reports, it is extraordinarily large.

Probably no one doubts but that gross lesions affecting the motor areas and producing the so-called "Jacksonian" epilepsy may be relieved by operation, and in this case the *modus operandi* is exceedingly simple and comprehensible. Even in cases of definite peripheral irritation giving rise to cerebral symptoms, it is comprehensible that the operation relieving such irritation may guard against the recurrence of the convulsion. Thus the excision of scar tissue has many times effected lasting cures, while the beneficial effects of circumcision and other minor operations for the relief of local irritation are generally acknowledged.

Dr. Wood (*Western Medical Reporter*, July, 1890), gives an interesting *résumé* of the many surgical means which have from time to time been employed for the cure of epilepsy.

Of the various operative procedures which have at one time or another been commended, may be mentioned phlebotomy, ligature of the carotids, ligature of the vertebral arteries, tracheotomy, trephining, circumcision, castration, removal of the ovaries, removal of the clitoris, nerve stretching and tenotomy of the ocular muscles. Hare (*Epilepsy, its Pathology and Treatment*), in the discussion of operation for the relief of possible peripheral irritation, writes as follows: "Like every other measure of relief, it is probable that a greater usefulness was claimed for it than was deserved, and probably many persons are lacking foreskins, ovaries or clitoris by reason of the search for peripheral enemies of the health."

As a curious fact, brilliant successes are recorded as resulting from all these operations, even when the parts operated upon were healthy, and there was no good reason to suspect that they were pregnant sources of reflex irritation.

In contrast to the surgical operations directed to the cure of epilepsy, is the long series of cases by which active counter-irritation by means of setons or issues, or by means of accidental wounds or burns, has also resulted in great amelioration in the severity of the disease. It would seem that in cases of idiopathic epilepsy any severe operation may modify the severity of the attack, or, if certain recorded cases can be believed, may permanently cure the disease.

The curative effect of operation *per se* is one which has been seen by every surgeon, and one which we are bound to believe exercises a most powerful influence.

If this doctrine be accepted, it would seem far better to perform operations which in themselves do not seriously endanger life, and since counter-irritation, especially when applied about the base of the skull, has been followed by many excellent results, it would seem desirable to so locate the seat of operation that, together with the mental and nervous effect, might be associated the derivative influence resulting from the local inflammation.

Of course, when gross lesions or distinct foci of irritation are present, these imperatively demand surgical attention, but in the absence of these an operation such as that of castration or oöphorectomy, performed solely for systemic effect, would seem to be entirely unjustifiable, since less severe procedures may advantageously take its place. —*University Med. Magazine*, October, 1890.

Action of Caffeine.

The physiological action of caffeine is summarized by MM. Germain Sée and Lapicque, as follows:

1. Caffeine in small and repeated doses, about 60 centigrams (about ten grains) a day, facilitates muscular work in augmenting the activity, not directly of the muscle itself, but of the motor nervous system, cerebral as well as medullary. The consequence of this double action is to diminish the sensation of effort, and to avert fatigue, which constitutes a nervous and at the same time chemical phenomenon.

2. Caffeine prevents breathlessness and palpitations consecutive to effort, which is of great importance.

3. It thus immediately communicates to a man who gives himself up to violent and prolonged exercise the aid that he requires.

4. In producing this excitation of the cerebro-spinal motor system, on which depends the augmentation of the muscular tonicity, the caffeine augments the waste of

the carbon of the body, and particularly of the muscles, but does not restrain the nitrogenous waste. It, therefore, is not, in the strict sense of the word, a means of saving.

5. A saving action in general can take place in the higher animals in a complete manner to prevent the injurious effects of fasting, only in a condition impossible to realize, namely, inaction or immobility, more or less absolute, where there is little expenditure without work. With caffeine we observe just the reverse, that is to say, intense work, which we will obtain only at the expense of the wear and tear of the organism. The animal machine can work only in consuming combustible matters, and it is precisely in promoting this combustion that caffeine permits muscular work even during fasting.

6. Caffeine has not, as is generally believed, the marvelous property of replacing food; it only replaces the general tonic excitation which the ingestion of food produces. It is admitted that it is the direct and instantaneous action of the aliments which stimulate the stomach and nervous system, and that their alimentary value is at first nothing; one might substitute one stimulant for another. Caffeine, far from sparing the reserves, will place a fasting man in a position to undertake his work only by attacking these reserves, the destruction of which it hastens by the excitation of the nervous system and by its medium that of the muscles; the organism will then soon use up its nutritive supply, and the caffeine will not prevent it. It is, nevertheless, of incontestable but temporary utility for the physical forces. — *Western Druggist*, September, 1890.

Venesection for Lead Poisoning.

Dr. W. E. Hughes says, in the *University Medical Magazine*, October, 1890, that venesection is a method of treatment of lead poisoning comparatively new, and little practiced and yet in the cases here recorded, so satisfactory, he thinks it well worth while to secure for it more prominent attention.

Dr. W. E. Hughes says, that a man 39 years old was admitted to the Philadelphia Hospital May 24, 1890, with symptoms of lead poisoning. Examination showed a very marked blue line on the gums; impairment of power in the right hand, less marked in left; wrist drop not absolute. The patient was able to raise his hand until it was in a line with his forearm. Attempts to raise his hand caused a spasm of the flexor muscles of the forearm and of the thumb. The spasm was quite severe, but did not last long, and the hand could then be brought on a line with the forearm.

On May 26, the patient was bled—f ℥ xvi being taken. One and a half hours later the hand could be raised nearly three inches higher than before he was bled, and muscular spasm was entirely absent. Sixteen hours after bleeding, flexion and extension were almost perfect. The grip was much better, and the pain in the abdomen was much less severe. Twenty-six hours after bleeding the condition of both arms was normal, and the patient had a normal bowel movement. Three days later the patient had a short but quite severe attack of colic. The bowels were moved normally; the blue line was gone. A few days later he was discharged cured.

In this case the results of treatment were most satisfactory. One bleeding cu rd instantly and permanently the spasm of the right hand. Not only this, but within few days the abdominal symptoms, and eve the blue line on the gums, had disappeared.

Dr. Hughes describes another case evidently of longer standing than the preceding one. Here the principal result of the bleeding was the restoration of power to the forearms. The abdominal symptoms were less relieved, still they yielded more rapidly to subsequent treatment than would be the case where bleeding had not first been resorted to. The man when admitted was markedly cachectic. This cachexia was uninfluenced by the bleeding, but has been since steadily disappearing under treatment.

In a third case there was comparatively no cachexia, and the results of bleeding were decided and permanent.

While these cases are too few in number to base any extended conclusions upon them, yet the results of bleeding were certainly much more satisfactory than those likely to be obtained by any other treatment. None of these cases had probably gone on to any organic lesion of the nervous system. The relief is probably due to two caues: First, to a relief of focal congestion in the cord or nerves; second, to a change in blood tension, facilitating the rapid elimination of the lead. No observations were made upon the lead in the blood, nor on the elimination of the lead after bleeding.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

KOCH'S METHOD FOR CONSUMPTION.

The danger of making announcements of proposed cures for diseases which have long defied medical science, is receiving a new illustration in the developments concerning the hopes received by Prof. Koch's announcement at Berlin, that he had discovered a method of treating tuberculosis by some sort of inoculation. Since that time the newspapers have contained various statements—some that the method was a success and would shortly be generalized, and others that Koch was asking for more time in which to perfect it, and again that he was endeavoring to generalize the principle so that it should include not only consumption, but also a variety of other diseases. Meanwhile those who have watched the history of similar procedures may possess their souls in patience, and not allow themselves to be too much elated at the prospect of speedily reaching a goal, towards which, for thousands of years, the medical profession has been striving, without making any very startling progress.

It would be so great a boon if some method could be devised by which the human system could be made incapable of contracting a disease which now destroys so large a proportion of the human race, or if it could be actually "cured" with such promptness as has recently been asserted, that it is no wonder investigators should hail Koch's announcement with delight, and be a trifle too ready to accept it.

But it may be well to remember when such scintillations from the laboratory appear and attract universal attention, that so far there is no known method of preventive inoculation which is in general and practical use, and which has been proved to be successful, if we except that of vaccination—which is so totally dissimilar in philosophical principle from the recently proposed methods with which the name of Pasteur is inseparably associated, that it is hard to understand how so many men belonging to a profession requiring a certain amount of logical acumen, should have overlooked the fact. Furthermore, if we call to mind Pasteur's announcements during the past twenty years, and remark how almost unheard of they are to-day, while the diseases—in grape vines, in silk worms, in swine, in dogs, and in men—for which they were proposed with such confidence, are still flourishing in various parts of the world, it seems cruel or unprincipled to announce with so great positiveness a preventive or curative treatment for consumption, unless it is such that its details can be published without any of those charlatan-like tricks which seem to be regarded by certain experimentors as perfectly legitimate.

We cannot but condemn the secrecy with which Koch is said to guard the details of his method of treating consumption, though

we would most earnestly hope that it might prove successful.

So far, however, we may say to the readers of the REPORTER there is in the accounts published about it nothing except food for curious and interesting speculation.

This is a judgment which is deliberately formed, and which we put on record now, partly as a protest against the haste with which some members of the profession accept illusory promises, and partly to prevent other men and women from running into what we believe to be a road to most bitter disappointment. But history is sometimes made very fast; and if we are wrong no one will rejoice more than we shall.

HERMAPHRODITISM.

In the *Gazette Hebdomadaire*, July 26, 1890, Dr. Pozzi gives an interesting review of hermaphroditism. The word is a compound of two Greek words, Hermes and Aphrodite (Mercury and Venus), and signifies a condition in which one person has the special sexual organs of the two sexes, each capable of functional activity. The possibility of such a condition was believed in thoroughly by the ancients, and is also maintained by some modern writers, such as Schultze, Rokitansky, Heppner; but all the cases referred to by these writers prove, when carefully studied, to be malformations of the genital organs, or arrests in development in the embryoneal stage in man; or they are the result of excessive development of certain parts in women. The individuals of the first class are incomparably more numerous than those of the second; that is to say, most pseudo-hermaphrodites are males with hypospadias.

While true hermaphroditism in human beings probably never occurs, Bland Sutton, who is well known for his studies in embryology and comparative anatomy, declares that it is the normal condition in the toad, and a very frequent one in the frog, which possesses both an ovary and a testicle. One should be slow, therefore, to deny that its occurrence in man is a possibility. Pozzi makes the following division of hermaphroditism: First, partial pseudo-hermaphroditism in which there exist only some peculiarities of one of the sexes with evident preponderance of those of the other. In this class are included two varieties, the gynandroi and the androgynes, according as the person belongs to the female or male sex. Second, pseudo-hermaphroditism, properly so-called, due to a perineo-scrotal hypospadias in which the external genital organs have an embryonal arrangement, and consequently appear like those of the female, and in which doubt is removed by finding the testicles. Third, pretended true hermaphroditism.

In gynanders the external organs of the woman simulate to a great degree those of man, and this is brought about by hypertrophy of the clitoris and prepuce which look like a penis, and union of the labia majora, and even at times of the labia minora, which look like a scrotum and hide the vaginal orifice. The resemblance to the male organs is still more pronounced when there is hernia of an ovary near the anus or into the labium majus.

Androgynes are men with one testicle or concealed testicles, who present certain external characteristics of women, among others, exaggerated development of the breasts. In these cases the masculine type of external genital organs exists, the scrotum is united and is surmounted by a penis with perforated glans. But the absence of testicles from the scrotum, the slight development of the penis, the median depression of the scrotum which simulates the two labia majora in apposition, the size of the breasts, which may be as much developed as in women, and, finally, the presence of folds like the labia minora, forming a ridge upon the scrotal raphe, all give the person a feminine aspect.

To the second class (pseudo-hermaphroditism properly so-called), belong the great

majority of the cases observed. It is made up of men with scrotal, or perineo-scrotal hypospadias. These persons are as a rule regarded at birth as belonging to the female sex, are baptized as girls and receive the costume and education of such. A great number of them have been married; nearly all have intercourse with men through the urethral orifice, which is deepened in the infundibulum, and still more by the vulvar depression which exists below this. But, at the same time, many have desire for women and perform coitus more or less incompletely. In some cases irregular menstruation is simulated by hemorrhage from the dilated and irritated urethra, and it is said that undeniable instances of feeble and intermittent menstruation have been observed in gynanders.

As regards the third class—of true hermaphrodites—it has been intimated already that it probably has no actual existence. Pozzi's opinion may be inferred from the fact that he affixes the adjective "pretended" to the class. It may be of historical interest, however, to note that Klebs has made a theoretical classification as follows: bilateral hermaphroditism, in which there exists on each side both a testicle and an ovary; unilateral, in which there is on one side both a testicle and an ovary; and lateral, in which there is on one side a testicle and on the other an ovary. The supposed cases of true hermaphroditism, as already stated, have not proved to be such on careful dissection by a competent embryologist.

THE ALLEGED FASTER.

It is now reported that Mrs. Wuchter, the alleged faster for more than six months, has begun to take nourishment in public, and has abandoned her pretense of being unable to talk. She now converses rationally it is said—and joins in the singing of hymns conducted at her bedside by the choir of a church near by. The probability is that she will soon begin to eat regularly and without concealment.

As to what she has been doing all these six months there can be no certainty, unless she or some one else describes it. Of course she has not lived without food for so long. No human being ever did. The case most resembling that of Mrs. Wuchter was that of the so-called "Welsh Fasting Girl," in 1869, whose parents claimed that she lived without eating; but when she was put under conditions of observation, by medical men who could not be deceived, she died in eight days—showing that she had a wonderful determination, but no power to live without food.

The crucial test of Mrs. Wuchter's veracity any time during her fast would have been to give her unwarned an emetic and a purgative, and to have observed the result. The nearest the REPORTER has been able—without aiming at a sensational effect—to come to this test, has been to procure a report of an examination of the feces which this woman actually passed. This report, made by Dr. Edgar M. Green, of Easton, Pa., will be found in the Department of Correspondence. From it, it will be seen, that the feces examined contained just what might be expected in the feces of a woman eating little, and suffering with chronic constipation. This precisely fits our estimate of the case, except that it leaves out of account the hysterical or fraudulent element, which we have no doubt is—or was—present in it.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

A TEXT-BOOK OF PRACTICAL THERAPEUTICS, WITH ESPECIAL REFERENCE TO THE APPLICATION OF REMEDIAL MEASURES TO DISEASE AND THEIR EMPLOYMENT UPON A RATIONAL BASIS. By HOBART AMORY HARE, M. D. (Univ. of Pa.), B. Sc., Clinical Professor of Diseases of Children and Demonstrator of Therapeutics in the University of Pennsylvania. 8vo, pp. 632. Philadelphia: Lea Brothers & Co., 1890. Price, cloth, $3.75; leather, $4.75.

After careful personal examination of this book, and taking unusual pains to see how it impressed other and more competent critics—we are compelled to say that we believe it is not a book to be commended.

This opinion is formed by reflecting upon its literary blemishes; its curious statements in pathology; its loose, and at times absurd, descriptions in symptomatology; and its unguarded and even dangerous suggestions for treatment. To cite examples of what we have in mind, we have here no sufficient space; but the reader who has not access to the book may perhaps get a clue to the peculiar character of its failings from the fact that the author—although Secretary of the Convention to revise the U. S. Pharmacopœia—repeatedly gives wrong names to drugs and makes blunders in the Latin of his prescriptions; and—although he has not been practicing medicine seven years—does not hesitate, in spite of the opinion of many practitioners of experience as well as that of Dr. Jacobi, who has made so careful and prolonged a study of diphtheria, to say that chlorate of potash should *never* be given in this disease; while, in the same section, he makes the suggestion that it may be treated with corrosive sublimate in doses ranging from $\frac{1}{10}$ to $\frac{1}{2}$ a grain!

A work on therapeutics should bear the marks of extensive experience, careful observation, wise generalization and exact statement. These marks, we regret to say, we cannot find in Dr. Hare's book. With this, its tone is so often supercilious or contemptuous towards those with whom the author does not agree, that he will have no right to complain of criticism which he may think harsh. A writer who shows so little respect for his predecessors in the art of medicine, who so boldly contradicts what men of much larger experience assert, who dedicates his book to a surgeon and describes surgical work as "slashing," cannot expect to be handled tenderly when he enters the lists of science or of literature.

A COMPEND OF EQUINE ANATOMY AND PHYSIOLOGY. By William R. Ballou, M. D., Professor of Equine Anatomy and formerly Lecturer on Physiology, New York College of Veterinary Surgeons, etc. With twenty-nine graphic illustrations. Small 8vo, pp. 205. Philadelphia: P. Blakiston, Son & Co., 1890. Price, $1.00.

This book forms No. 12 in the Blakiston series of quiz-compends. It is intended for the use of students of veterinary medicine. The illustrations have been selected from Chauveau's well-known *Comparative Anatomy*. The author's past experience as a quiz-master and teacher of anatomy has enabled him to compile a book which will no doubt be of great assistance to students, and will be properly appreciated by them. We confess to a dislike of the expression "Equine" Anatomy; but perhaps it is the result of prejudice.

THE ESSENTIALS OF MEDICAL CHEMISTRY AND URINALYSIS. By Sam E. Woody, A. M., M. D., Professor of Chemistry and Public Hygiene, and Clinical Lecturer on Diseases of Children, in the Kentucky School of Medicine. Third Edition, revised, enlarged and illustrated. Small 8vo, pp. viii, 157. Philadelphia: P. Blakiston, Son & Co., 1890. Price, $1.00.

The first ninety-six pages of this little book are given to a review of inorganic chemistry, including the hydrogen and oxygen group of elements, the chlorine group, the sulphur group, the nitrogen group, the carbon group, metals of the alkalies, metals of the alkaline earths, metals of the earths, the zinc group, the iron group, the copper group, and the silver group. The following twenty-two pages, which form Part II, are taken up with organic chemistry—hydrocarbons, alcohols, ethers, aldehydes, organic acids, the carbohydrates, glucosides, nitrogenous bodies, and alkaloids. Urinalysis is compressed into fourteen pages, and completes the book.

The descriptions in the text are clear and terse, and the illustrations have been chosen with excellent judgment. In the part devoted to Urinalysis, a surprising amount of information is given in a small space. The spermatoza figured on page 143 have rather flat heads. The book is well printed, and presents a better general appearance than most works of its class. The fact that it has reached already a third edition, indicates that it has met with favor.

Correspondence.

The Alleged Faster.

To the Editor.

Sir: In the number of the Medical and Surgical Reporter, September 27, 1890, there was an Editorial on the alleged case of fasting near Allentown. I have thought, therefore, that possibly an item of information concerning the fecal movements of this case might not be uninteresting. Not long ago Drs. E. W. Evans and B. Rush Field, of Easton, Pa., visited Mrs. Wuchter, the alleged faster, and obtained possession of a portion of her stool, which was given to Prof. J. W. Moore, M. D., of Lafayette College, and to me for examination. It was a very hard mass, about one-half an inch in diameter, having a natural color (though at one point very slightly tinged with blood) and with characteristic odor. It weighed forty grains, and was said to be about one-fourth of the entire stool. It is stated that the woman has movements similar in size and character every twenty days. Microscopic examination revealed:

(a) Vegetable tissue in great abundance. This consisted of spiral ducts in great numbers. Many of them were uncoiled. Some of them, however, were not at all uncoiled, but were even still united in pairs side by side. Some large patches of such ducts arranged in parallel groups were to be seen. There were also portions of the veining of leaves, with the parenchyma digested off. Portions of cellular tissue, however, with the cells still grouped together and the edges of the mass smooth and sharply cut, were also to be found.

(b) Crystals of the triple phosphates were present in great numbers.

(c) Fat crystals of the characteristic form.

(d) Blood corpuscles.

(e) Mucus.

(f) Granular detritus in moderate amount and perhaps muscular fibres.

Yours truly,

EDGAR M. GREEN, M. D.,
Pathologist of St. Luke's Hospital,
South Bethlehem, Pa.

Easton, Pa.

Eulenberg and Hermann.

TO THE EDITOR.

Sir: Permit me to state the following in reference to your Berlin Correspondent's assertion that Professor Eulenberg had recently pronounced a young officer named Hermann to be sane, and that the said officer would be restored to his rank and estate in Austria, in consequence of said opinion.

1. Professor Eulenberg is not, and never was regarded as, an alienist.

2. Hermann had been pronounced insane on such high authority, and so repeatedly confined in asylums, that it was the height of audacity for Professor Eulenburg to give (as he did) a retrospective opinion.

3. Unfortunately for Professor Eulenburg his protégé Hermann has since published a book, now in my possession, the color of whose binding is black while the lettering is blood red, whose contents would outweigh a thousand contrary "expert" opinions.

4. Hermann is a "paranoiac" and his sequestration probably prevented just such an act as the recent shooting of Dr. Lloyd.

5. It was not until Hermann found that he could not secure the services of a real alienist to pronounce him sane, that he appealed to one whose reputation as a neurologist might perhaps dazzle the laity, but which can scarcely mislead those of us who are aware that a long experience with myelitis and migraine does not necessarily endow one with diagnostic acumen in the field of mental disorder.

You will probably hear a great deal more of the Hermann matter. For the present I think your readers may rest content that institutions which, like those attacked by Hermann and his unlucky associate Eulenburg, are officered by Meynert, Ganster and Krafft-Ebing are above the criticism of the latter and a safe keeping-place for the former.

Yours truly,

E. C. SPITZKA, M. D.

New York.

NOTES AND COMMENTS.

Deformity of Face Treated with Apparatus.

L. P. Blair, D. D. S., a dentist, describes in the *International Dental Journal*, September, 1890, the following very interesting case.

A young woman, twenty-six years old, came to him with a very peculiar condition of face. The portion which extends from the median line of the lips to the angle of the mouth and from the infraorbital canal to the mylohyoid ridge, was entirely gone. She desired to know if he could do anything for her. Up to the age of six years she had been perfectly healthy; at that time she was taken with tyhoid pneumonia. The physician in attendance gave calomel and quinine; forty-six hours after which a blue spot was noticed on the inside of the cheek. The next morning it was visible on the outside of the face, and before night the portion of her face extending from the eye to the condyle of the jaw and along the mylohyoid ridge and median line of the face developed a line of sloughing, and in a few hours entirely dropped out, exposing the bones. The temporary teeth dropped out and the motion of the jaw ceased and it became ankylosed.

The young woman had had two attempts made with plastic operations, both of which were only partially successful. When she applied to Dr. Blair the lateral, canine and two bicuspid teeth in the left superior maxilla had been removed in order to allow her to eat, drink and articulate. For twenty years she had lived, eating through that small aperture.

She wanted to know if something could not be done to hide that ugly gap. Dr. Blair told her he thought it possible. First he took a plaster cast of the face and molded paraffine and wax upon it until he had the face as near perfect as he could get it. He then took a cast of the face and obtained his die. He next placed sheet wax upon this and forced it into position, thus getting a skeleton form; then trying it upon the face, he found it to be correct. He subsequently made two crowns to fit the lower bicuspids and placed them in position; then two bands to fit upon the crowns in the form of spring clasps, leaving an arm from each extending through the wax form. These arms he fastened securely and re-

moved the form with the clasps in position. Having now the model he desired, he inverted in plaster and proceeded as in plate-work. He rough-finished and sent it to an artist to be painted. The artificial portion of the face was made of pink and brown rubber painted. He simply filed off the outside, polishing thoroughly the inside.

The result was that the young woman had a false part that so nearly resembled the other side of the face that none but the very observing would notice any difference. This fixture obstructed the aperture for feeding; to obviate this difficulty Dr. Blair removed the right centrals, laterals and canines in upper and lower jaw, thus allowing the patient to eat, drink and articulate without removing the appliance. When he reported the case she had been wearing it five months with perfect satisfaction. His report is accompanied by excellent photo-lithographs which show the face before and after the operation, and show a very remarkable and successful result.

Treatment of Dysentery.

In a paper read before the Medical Society of the County of Kings, and published in the *Brooklyn Medical Journal*, October, 1890, Dr. H. A. Fairbairn, attending physician to St. John's Hospital, says that the object of his paper is to give practical endorsement to the statement of Dr. Whittaker, in his article on "Dysentery," in Pepper's *System of Medicine*, that irrigation of the large intestine and the thorough flushing out of its contents are now admitted as the most valuable method of treatment. From personal observation, he believes that this method is not in such general use as one would suppose. He desires to record his success with it after repeated trial, and trusts that those who have made use of it will add their testimony to that already recorded, and that it may prove to all, as it has to him, a remedy to be relied on as sure and prompt.

He says: "To be of use, the enemata must be large and frequently repeated. In some cases I have used them at first every two hours, increasing the interval with the improvement; in others every four hours. As to the quantity, that must be measured, to some extent, by the tolerance of the patient. I find that it is well for the physician to demonstrate this. People, as a rule, have a mistaken idea as to the capacity of the large intestine. If verbal directions simply are given, at the next visit it will be found that a few ounces are announced as a result of the trial. The measure of the capacity seems to be based on that of the external aperture, and the idea of danger is coupled with the introduction of more than a pint: a point well taken in chronic dysentery perhaps, where, no doubt, it would be dangerous to distend the walls of the intestine, weakened as they are liable to be by deep ulceration. But if the case be seen in the early stages, the quantity safely used will be measured by pints instead of ounces. The capacity of the large intestine, as a rule, is about six pints. Three or four pints will suffice in this treatment. As to the temperature of the water, moderate warmth, from 100° to 105°, I find most acceptable, except possibly in the first or second administration, when quite low temperature appears of benefit.

"As to the instrument used, the common syringe serves a good purpose. The fountain syringe needs to be used with care. People little know of the great hydrostatic pressure it brings to bear. The hand on the syringe-bulb is a better guide. The position of the patient on the right side, with the back to the nurse, is the most convenient. The introduction of the first few ounces is met by the patient with loud protests; these decrease with assurances of safety and benefit. I have never used medicinal substances in the water, except in one case, where alum proved of benefit. In chronic cases I have never pushed the treatment. I imagine that very few chronic cases would exist if the cases are treated locally from the beginning. So much for the local treatment. I use it from the first and persist in it. Its annoyance decreases with the repetition.

"Now as to the general treatment: I confine my patients to bed. I deprive them of food as much as possible, whiskey (well diluted), in small quantities, being allowed; this is food, is supportive, and allows the lower canal much needed rest. Milk I do not use unless peptonized, and then only in very small quantities. Prepare it as you may: the excrement will be large if the quantity taken is. I rarely allow more than a quart in the twenty-four hours. If the patient will rest without food for forty-eight hours, I find it of advantage. The fast, as a rule, is not a difficult one, the appetite

being in abeyance. The liquid preparations of beef I do not use in intestinal involvement; with their concentrated salts they act as an irritant: they distress more than they benefit. Eggs, scraped beef, or, when these are objected to, the steak, roast and chop with bread, make up the dietary."

Certain medicinal measures by the mouth are of advantage. Dr. Fairbairn administers a cathartic at the commencement of the treatment. If there be nausea, calomel in small and frequently repeated doses is the drug chosen, otherwise magnesium sulphate. Salol is then ordered and opium in some form if the pain demand.

To sum up: The treatment is simply the application of the antiseptic method—the rational and scientific treatment of a disease which exhibits itself mainly as an inflammation of the large intestine, where much of the havoc is wrought, much of the constitutional disturbance being due to the absorption of septic products.

A Word for the Preceptor.

Dr. I. W. Chisholm, of New Concord, Ohio, writes to the *Columbus Medical Journal*, October, 1890:

"Our medical colleges are fast adopting the three-year graded system of study, and, as we understand it, exclude all preparatory study in the office of the home practitioner. We are furthermore told that this system of study will place the cause of 'medical education' on a higher basis. Then why is it that some we know, who studied under the old regime, found on entering some of our medical colleges that they were as far advanced as those in the 'senior year' of this highly lauded and much to be admired (?) graded system? If this course of the medical Latter Day Saints is to become universally adopted, it should not preclude the preparatory course of study of the home preceptor, but should require it, because by the evidence we have adduced it is the proper method, and we challenge contradiction.

"In our own individual opinion, publicly expressed, what is most needed in our course of medical training for a higher advancement and usefulness, is more of the practical and a great deal less of the didactic, to which a student is compelled to sit and listen. As an illustration, think of a professor giving eight or ten lectures, each of one hour's length, on the pelvis, when all could be said that is really of any practical benefit, either to the coming practitioner or suffering humanity, in one or not to exceed two lectures.

"There is, in my opinion, a vast amount of literary shoddy woven into the texture of the make-up of the didactic lecture-course. Give the student the scalpel, and bistoury and forceps in surgical and obstetrical operations; let him feel the pulse, diagnose, prognose and prescribe at the bedside—all under the care and guidance of the professor; and when he leaves the halls of his Alma Mater he will have the advantages of a trained and experienced eye, touch and judgment, instead of a skeleton knowledge of the 'healing art,' clothed with an appearance of literary down."

International Congress of Hygiene.

The Seventh International Congress of Hygiene and Demography will be held in London during the week beginning August 10, 1891. The Governments of all countries and municipalities and all Public Health Authorities, Universities, Colleges and Societies occupied in the study of the sciences more or less immediately connected with Hygiene are invited to co-operate and appoint delegates to represent them at the Congress. The Prince of Wales will preside.

A Committee of Organization has been formed, of which Sir Douglas Galton is Chairman, and Prof. W. H. Corfield and Mr. Shirley F. Murphy are Honorary Secretaries. An exhibition of articles of hygienic interest will be held in connection with the Congress. The last of these Congresses was held in Vienna in 1887, and was attended by over 2,000 persons, and it is expected that the London meeting will be one of great magnitude and importance.

Removal of Tumor of the Brain.

In the *Australasian Medical Journal* for July, 1890, Dr. Graham and Mr. Grubbe record a case recently under their care in which a hydatid tumor was removed from between the dura mater and pia mater of the brain. The patient was a lad sixteen years of age, who suffered from severe headache, nausea, vertigo, double optic neuritis with atrophy, loss of memory, mental dulness, and paresis of the right arm and leg. A tumor involving the left motor area was diag-

nosticated, and Mr. Grubbe trephined over it. He found the bone not more than one-sixth inch thick, and on opening the thickened dura mater a single simple hydatid cyst was seen, and was easily extracted. The pia mater was intact. The cyst measured four inches in diameter, and held nineteen ounces of fluid. The patient recovered. After six weeks he was able to get up and walk, his memory returned, and in all respects he was well except for his blindness.

Such a case as this was extremely favorable for surgical treatment, as its situation greatly facilitated exact diagnosis, and its removal was unattended with any injury to the brain itself. It is believed to be the first recorded case of the kind. Dr. Davies Thomas records three cases of recovery from cerebral hydatids, in one of which the cysts were passed through the nose and mouth; in two others they were removed through incisions in the scalp after the tumors had perforated the cranium.—*Lancet*, September 13, 1890.

Strangulated Hernia.

At the last meeting of the Buffalo Medical and Surgical Association, Dr. W. S. Tremaine made some remarks on strangulated hernia. He said (as reported in the *Buffalo Medical and Surgical Journal*, October, 1890), that he was well aware that he had not chosen a very new subject, but he also knew that it was not worn so threadbare but that it might afford material for some practical points for the general practitioner. Twenty or thirty years ago our teachers said that in cases of strangulated hernia, we were to continue our efforts at reduction for a long time, and avoid, if possible, an operation. There remains with the older men, more or less of the traces of this early teaching, and he has occasion as a consultant to meet with it now and then. The first point of his remarks was directed to the absolute necessity of early operation in cases of strangulation, if gentle taxis failed to reduce. No case of strangulated hernia will die from an operation, if in proper hands; but will surely die if let alone, and especially if too great and vigorous efforts at reduction are used. Every man who practices when he is not within easy reach of a competent surgeon, should know how to operate for strangulated hernia. A practitioner on encountering a case of strangulated hernia, should either send at once for a consultant, or explain the risks of an operation and the necessity for one. Then, if under chloroform a reduction with slight and exceedingly gentle taxis cannot be secured, the hernia is to be attacked, the sac opened, and the constriction found and released. He related a case where, from the severe and prolonged efforts at taxis, he found the gut black, and he hesitated whether to return it to the peritoneal cavity to make an artificial anus. He remembered Sir Astley Cooper's axiom: "That the belly is the best place for a gangrenous gut,"[1] and slipped it back. The patient made a good recovery. Dr. Tremaine's second point was in relation to the so-called "radical cures of hernia," which he believes ought to be termed "attempted radical cures." We are as yet a long way from being at the bottom of this matter. There is at present a sort of rage for operating on cases of hernia, mostly because of the simplicity of the operation, and the comparatively small risks. In cases with small sacs, little gut, or perhaps mostly omentum, he would not operate. There is now a current setting in the other direction, and a re-action against this promiscuous operating is taking place. He mentioned a case where it was exceedingly difficult to isolate the sac, the hernia was omental, and had probably never been entirely reduced; he found the cord, the testicle, the omentum, and the sac, one intricate, tangled mass, and was compelled to remove the whole. It was a question of moment, in this case, whether he ought to have removed the testicle without the patient's consent; all of the attending circumstances certainly justified his decision to do so. There is no fixed point at present from which we can decide whether we ought to attempt a radical cure or not. Dr. Tremaine believes that, if the patient be a person who works by his brain and not by arduous labor, and whose rupture is easily retained by a simple truss, that such a case should be left unoperated. If, however, the patient be one who does great muscular labor, and who cannot maintain his hernia within the abdomen easily by a truss, then in such a case we should attempt a radical cure. In cases of strangulation and irreducible cases, it is a question yet unsettled, whether, when operating for relief, we should attempt to get a radical cure also.

[1] [Did he remember how long ago Sir Astley Cooper practiced surgery?—Ed. REPORTER.]

In these last cases deaths do occur, and we cannot always say from what cause, either.

The patient's life is always to be the first consideration, and whatever arises, the consultant's judgment ought to prevail.

Effect of Medical Legislation in Minnesota.

The *Northwestern Lancet*, October 1, 1890, says:

The publication of "The Official Register of the Physicians of Minnesota," a book just distributed among the medical practitioners of the State, offers a good opportunity for reviewing the work of the State Medical Examining Board, whose labors now extend over a period of seven years, the first Medical Practice Act in this State having been approved in March, 1883. The effect of the Minnesota law upon the medical profession of the State is of unusual interest, for the reason that the statute now in force, that of 1887, is regarded as a model of its kind by all friends of medical legislation, a real attempt to protect the people from medical ignoramuses and charlatans, since it recognizes no diploma but requires every candidate for license to practice medicine to pass a thorough and it is believed not too rigid examination in all branches of medicine. Whether these examinations are fair tests of the fitness of candidates to practice it is open to the individual judgment of the members of the profession in the State to decide, since the papers of the examinations have frequently been published in these columns during the last two years. These papers have been a good deal criticised and have often deserved it, but at least one thing can be said, that the Examining Board has honestly endeavored to make a fair test of the fitness of the candidates who have come up before it.

One of the first points of interest in investigating the operation of the law is its effect upon the number of physicians in the State in relation to the population. As might be expected the effect has been to diminish that number, that is to reduce the proportion of physicians to population. In 1883 the ratio between physicians and inhabitants was 1 to 650; according to the register just published the ratio is 1 to 1,250. The ratio for the whole United States is 1 to 520, so that when compared to the rest of the country Minnesota appears to offer a favorable field for the physician seeking a place in which to settle. But compared with other countries the ranks of the medical profession are crowded even in Minnesota. In France there is one physician to every 2,000 people; in Austria one to 2,400; in Germany one to 3,000; in Italy one to 3,500, while in Sweden there is but one medical man to every 7,000 inhabitants.

No one can doubt that the great benefit from the law has been through its indirect effects, that is that the knowledge that the law existed has prevented many medical incompetents from trying to come to the State. The Medical Examiners have been gratified to find that the number of applicants for license increases, and with this increase in the number comes a steady rise in the average attainments of the candidates. The well-qualified physician, the graduate of a high-grade medical school, knows that he has nothing to fear from the examinations of the Board, and he is attracted to this State by the knowledge that he will not have to compete with quacks and medical pretenders. Meantime what becomes of the quack? Driven from Minnesota, Illinois and other States whose peoples are protected against imposition, he takes refuge in such States as Michigan and Massachusetts where there is no restraining medical law. Within a few years hundreds of medical charlatans have thus been driven away; not daring to appear in Minnesota in person, their only way of reaching this State is by advertisements in the newspapers, inviting the afflicted hereabouts to go to the cities of other States which they, the quacks, have made harbors of refuge. The general adoption of statutes like that of Minnesota, an event which is bound to come in the near future, will rid the country of one of its worst pests, quack doctors.

Immigrants and Skin Diseases.

In concluding an interesting paper on the skin diseases of immigrants (*Journal of Cutaneous and Genito-Urinary Diseases*, October, 1890), Dr. James C. White says:

Unless some more stringent laws are made to keep out of our country the pauper and dirty populations of Europe, the direct importation of the diseases we have been considering, and those which may arise as well from the filthy habits they bring with them and transmit to their children, must follow with increasing magnitude. If the proposed plan of the U. S. Marine-Hospital Service, to station physicians in every European port

from which immigrants embark to this country for the purpose of keeping back improper classes, be made sufficiently authoritative and restrictive it cannot fail to be of vast benefit. It is certainly as important to protect ourselves by legislation against the introduction of ignorance, filth, and disease, as against cheap labor, if we would keep our civilization upon a high plane. The Chinese have set us an example of building walls, which we might better erect against other nations than theirs.

In conclusion, I venture to suggest for the consideration of this association the propriety and importance of memorializing the National Government with regard to taking such steps as may be possible and practicable for the establishment and execution of the following measures:

1. To cleanse all immigrants of animal parasites on landing by treatment of person and clothing.

2. To retain in quarantine all immigrants with other contagious diseases, including venereal affections, a sufficient time for treatment.

3. To return to their homes all persons affected with such contagious diseases as it is impracticable to treat in such way, as leprosy, tuberculosis, and advanced syphilis.

4. To provide for efficient medical inspection at foreign ports of emigration, with the power of arresting importation of dangerous diseases to this country.

Prevention of Syphilis.

In the Section on Hygiene at the recent International Congress, an interesting and important debate took place regarding the matter of licensing houses of prostitution. Dr. Thiry, of Brussels, earnestly advocated the licensing system with sanitary inspections twice a week. Dr. Kaposi, of Vienna, took similar grounds. Dr. Thiry would not allow any prostitute to be licensed under the age of twenty, but Kaposi thought that sixteen was a sufficiently advanced age. The views advanced by the above gentlemen were opposed by several others, among them Dr. Drysdale, of London, who asserted that, according to his investigations, there was as much syphilis in Paris, where prostitution is regulated, as in London, where it is not. A vote of the Section was finally taken, and it was shown that a great majority of the members were opposed to regulation.

This is the view which in the present state of society is most in accord with justice, common-sense, and experience. Licensing and sanitary inspection tend to produce secret prostitution; and besides, such methods enforce penalties upon women but not upon men, and are therefore most unjust.—*Medical Record*, October 4, 1890.

A Hydrophobia Story.

The newspapers of October 17, report that Private Frank O'Neill, Battery C, Fourth artillery, U. S. A., stationed at Fort McPherson, died of hydrophobia at Atlanta, Ga., on October 16. O'Neill was bitten by a dog some time ago, but did not experience much trouble from the wound. Later, however, it began to trouble him, and he was compelled to go to the hospital. He then began to show signs of madness, frothed at the mouth and developed wonderful strength. He was put in a padded room in the hospital. He threw himself violently against the walls, but the padding kept him from killing himself. He positively refused to eat or drink, and it required seven strong men to hold him down. He broke loose from them once and overturned the stove, setting fire to the hospital. This was extinguished, and finally, by forcing him down, putting a mattress on him and eight men piling themselves on this, they succeeded in holding him. In this position an opiate was injected into his arm and he was quieted. In this condition he died.

[This is quite a typical hydrophobia story, probably exaggerated and somewhat distorted by the news-gatherer; but the principal features: of maniacal manifestations, violent restraint, administration of opium, and death are no doubt correctly stated.—Ed. Reporter.]

Xerostomia.

Xerostomia is an affection extending over years, hitherto observed only in elderly women, attended with cessation of the secretion of saliva. Diminution of the nasal and lachrymal secretions may also be present. In two cases reported by Dr. Seifert in the *Wiener Klinische Wochenschrift*, No. 46, 1889, of which an abstract is published in the *Deutsche Medizinal-Zeitung*, Sept. 25, 1890, the patients were elderly men. The main symptoms were an extremely distressing dryness of the mouth and fauces and of

the nasal cavities, with difficulty of deglutition and articulation. The surface of the tongue was red, fissured and dry; the mucous membrane of the mouth, fauces, and in one case of the nasal cavities, was pale, shining and transparent, without a trace of secretion. An evening dose of eight or nine drops of a solution of twelve grains of hydrochlorate of pilocarpine to the ounce of distilled water relieved the symptoms in both cases, without unpleasant secondary manifestations. Notwithstanding the administration of the drug for a long term of years, there was no dimunition in its efficacy.

Ignorance and Crime.

The Philadelphia *Ledger*, September 30, says that among the papers read before the Prison Congress was one which refuted the widely accepted theory that education, if it does not promote crime, at least does nothing to suppress or limit it. This is a conclusion sometimes drawn from prison returns, stating that seventy or more per cent. of the convicts are able to read or write, and ignores the relative number of illiterates in the whole community. When the examination is carried back of the prison returns it is found (in one case) that 95 per cent. of the community being able to read and write furnished 70 per cent. of the convicts, while only 5 per cent. of the community (the illiterates) furnished 30 per cent. of the convicts. It should be observed that many other conditions besides illiteracy combine to put the ignorant in the criminal class in undue proportion, but the statistics in so far as they show the influence of public education upon crime and criminals are favorable and not otherwise. Too much stress should not be laid upon this point, however.

NEWS.

—Dr. R. J. Levis, the well-known surgeon, died at his home, Cedarcroft, near Philadelphia, on the morning of November 12.

—It was reported on November 4, that a steamer with a thousand immigrants on board had been detained at quarantine at New York because some of the passengers had small-pox.

—A man died at the Brooklyn City Hospital, October 30, under the administration of ether for a surgical operation. It is said that only four drachms of ether had been used when the fatal result occurred.

Dr. J. E. Emerson, Detroit, Michigan, Chairman of Committee on Eligible Fellows, will forward to any applicant copies of the amended Constitution and By-Laws, Lists of Members and other information as to the Academy.

—The resignation of Dr. W. M. L. Ziegler as Instructor in Otology in the University of Pennsylvania was accepted November 4. Dr. Seneca Egbert was assigned to supply the chair of Hygiene during the vacancy in that Professorship.

—The Constitution of the American Academy of Medicine was altered at the last annual meeting, so as to admit, in addition to those possessing the degrees of A. B. and A. M., those who can present evidences of preparatory liberal education equivalent to the same.

—The result of seven years' operation of the Medical Practice Acts in Minnesota has been to reduce the ratio of physicians to population from 1 to 650 to 1 to 1,250. During the last three years 205 candidates presented themselves for examination and 77 of these were rejected.

—The Trustees of the Jefferson Medical College on November 3 postponed until December 8 the election of a Professor of Materia Medica, General Therapeutics and Hygiene (the chair lately filled by Dr. Bartholow). Eight physicians have been nominated for the vacant Professorship.

—An infant child of a man living near Rockport, South Dakota, was recently killed by a Newfoundland dog, which proceeded to devour the babe. While the animal was engaged in its work it was discovered by the mother, who fell senseless, and afterwards is reported to have become a maniac.

—A young woman died under the influence of chloroform while undergoing a slight surgical operation in a hospital in Chicago, on November 7. Her parents took her to the hospital to have a small mole removed from her right cheek. The mole was excised, but when the physician sought to revive the patient she was seized with a convulsion and expired.

—Dr. Justus E. Gregory, of Brooklyn, recently died suddenly, from the effects of chloroform, in a drug-store. Dr. Gregory had been suffering with neuralgia in the temple, and to relieve the pain was accus-

tomed to inhale chloroform, in the use of which drug he was considered an expert. He went into the store, and, saying that his eye pained him, asked for the chloroform, and sat down to inhale it. A short time later he was found dead.

—The newspapers report on November 10 that Prof. Bergmann inoculated fifteen consumptive patients on November 6 by Koch's process, and on the following day exhibited one of the patients before a number of physicians in order to show the change that had resulted within twenty-four hours. The *Borsen Courier* says it has authority for the statement that Prof. Koch's remedy has proved to be a success. A famous German surgeon, it says, cured within five days a case of lupus or necrotic tubercular destruction of the tissues of the face. The *National Zeitung* says that Prof. Koch, although he has performed a number of cures, does not yet consider the time come for the publication of his researches. Although the remedy has been applied to patients in the Charity Hospital and in some private cases, its composition remains a profound secret.

OBITUARY.

HENRY JACOB BIGELOW, M. D.

Henry Jacob Bigelow, M. D., died at his country house in Newton, Mass., on Thursday, October 30, at the age of seventy-two years. The *Boston Medical Journal* says, in its issue of November 6, that for the last few years Dr. Bigelow has been subject to gastric disturbances and attacks of hepatic colic; and for several days before his death his stomach refused to retain food. A post-mortem examination showed the presence of gall-stones, and an inflammation of the common duct, which had extended to the smaller bile-ducts, and was attended with the formation of several small abscesses of the liver. There was also a fibrous stenosis of the pylorus and a slight consequent dilatation of the stomach. The pulmonary affection which was the cause of a temporary abandonment of his medical studies in his early manhood had left its traces at the apices of his lungs.

Dr. Bigelow was born in Boston March 11, 1818. He prepared for college at the Boston Latin School, and was graduated at Harvard in 1837. He received his medical degree in 1841, and then went to Europe, where he spent three years in the further study of his profession. After his return to Boston he was, in 1845, appointed instructor in surgery in the Tremont Street Medical School. This position he held until this school was united with the Medical School of Harvard University. In 1846 he was appointed surgeon to the Massachusetts General Hospital. In 1849 he was appointed Professor of Surgery, the two chairs of Surgery and Clinical Surgery, previously held respectively by Dr. J. C. Warren and Dr. George Hayward, being united.

A few months after his appointment as surgeon to the hospital, ether was first used in the hospital amphitheatre for surgical anæsthesia. Dr. Bigelow was one of the first to see the value of the discovery, and he was specially influential in extending the use of anæsthesia in surgical operations. It was chiefly through his paper on the subject that the knowledge of the wonderful discovery was made known.

Dr. Bigelow has not been a very voluminous writer, but his contributions to surgical knowledge have completely changed surgical practice in several particulars. His interest in anæsthesia and anæsthetics has been repeatedly shown by various articles on ether, nitrous oxide and on rhigolene, a petroleum naphtha for producing anæsthesia by freezing. The famous case of Dr. Harlow's of the passage of a crowbar through the head, was made known chiefly through Dr. Bigelow's interest and study of the case. His work on *Dislocation of the Hip-Joint* has banished pulleys and rings from the clinic-rooms. His litholapaxy has revolutionized the treatment of stone in the bladder, and given rise to a literature that far exceeds in volume the united writings of its famous inventor.

Beside these claims to respect, Dr. Bigelow was acute, clear-sighted and inventive, and capable of close and severe study. As a teacher he had the power of impressing himself upon his pupils, and of leaving in their minds a sentence or a few words that contained the truth he wished to convey.

He resigned his professorship in 1882, and his connection with the Massachusetts General Hospital in 1886. During the succeeding years he has led a quiet life, for the most part at his country house, where he has taken great interest in the pursuits of a country life, and in these details he has shown the same marked individuality that characterized his surgical career.

FAIRCHILD'S

PANCREATIC TABLETS.

Afford a convenient, effective, and elegant means of administering the ferments of the pancreas.

These tablets can be given at any interval prior or subsequent to the ingestion of food, at the discretion of the physician, without entailing inconvenience to the patient.

In cases of intestinal indigestion, what can be a more rational practice than the introduction of the pancreatic ferments at the time when the gastric digestion is spent, and no obstacle is offered to their passage into the intestinal tract?

Pancreatic ferments bear no dependence upon an alkaline reaction. They are exceedingly active in neutral solutions and are not rendered inert by a merely acid reaction. It is, therefore, only at the height of *normal* gastric acidity that the pancreatic ferments may be theoretically held to be inoperative in the stomach. The ferments of the pancreas—known to digest rapidly every form of food, starches, fats, beef, milk, fibrin, etc., have proven useful as remedies, *per se*, notwithstanding the prejudice of theoretical views and conclusions based upon experiments under conditions purely artificial and differing in important respects from those in which their employment is indicated.

CLINICAL LECTURE.

DIGITALIS IN VALVULAR DISEASE OF THE HEART.[1]

BY FREDERICK P. HENRY, M. D.,

PHYSICIAN TO THE JEFFERSON MEDICAL COLLEGE HOSPITAL, AND THE PHILADELPHIA HOSPITAL.

The patient before you, a colored man æt. about 60, when admitted a few weeks ago, presented every symptom of failing cardiac action. There was intense dyspnœa, amounting in fact to orthopnœa; the lungs were congested; the pulse was rapid, feeble and irregular, and there was general anasarca. The legs were enormously swollen; there was some ascites, and over the sternum the finger on pressure seemed to bury itself in the waterlogged tissues. Another most significant fact was that the urine was greatly diminished, amounting at the time of admission and for a day or two thereafter, to about fifteen ounces per diem. The cause of the alarming symptoms to which I have just referred is plainly evident. On examining the heart I found a distinct blowing murmur, synchronous with the first sound, and heard with greatest intensity over the apex beat, which is somewhat outside of and below the usual situation. This same murmur may also be heard in the left axillary region as far back as the anterior border of the latissimus dorsi muscle. The three cardinal points of this murmur and, in fact of all murmurs, viz., the time of its occurrence, the area of its greatest intensity, and the direction of its transmission indicate unmistakably a condition of mitral insufficiency. At each ventricular systole a certain amount of blood regurgitates into the left auricle, and as a matter of course interferes with the pulmonary circulation. Such backward pressure is more serious in the pulmonary than in the general circulation, because the veins of the former are destitute of valves and pursue an unusually straight course.

In the case before us the symptoms of failing cardiac action arose suddenly, although the lesion on which they depend is an old one. In other words, they represent an acute exacerbation of a chronic ailment. In every acute affection which you are called upon to treat, you should endeavor to ascertain whether the disease has originated *de novo* or has for its foundation some organic defect. You can readily understand without my giving you any special examples, how the prognosis of permanent recovery will vary in accordance with the result of such examination.

Compensation in this case was well maintained until a certain day, a few weeks ago, on which the man was employed in cleaning out a cold, damp cellar. It was worse than damp, for he tells us that while engaged in this work, he was standing in cold water. Immediately after this exposure the symptoms above mentioned made their appearance and had their origin in the circulatory point of least resistance, *i. e.*, the pulmonary vessels, which were already in a state of chronic congestion. There was nothing inflammatory in the nature of this attack, as is proved by the temperature, which has been, as you may see by this chart, persistently subnormal. The prolonged impression of cold upon the cutaneous vessels—in a word, the chill—was enough to give the balance of circulatory power to the veins. There is a certain physiological antagonism between the arterial and venous systems, the maintenance of which is essential to a perfect circulation. The tendency of every variety of valvular heart disease is to destroy this antagonism and the object of treatment is to restore it. In

[1] Delivered at the Philadelphia Hospital, Nov. 12, 1890.

the case before us this antagonism was lost: the arteries had given up the struggle; their tension was relaxed; in short, the whole circulation was of a venous type. This was indicated especially by the subnormal temperature, the scanty secretion of urine, and finally by the general anasarca. The object of treatment was to strengthen the heart, and at the same time to increase the arterial tension. This has been most successfully accomplished by a drug—digitalis—which, except in rare instances of unusual susceptibility or idiosyncrasy, is still *facile princeps* among cardiac tonics. There are certain facts concerning this drug and its indications to which I will refer in connection with this case in which its employment has been so successful. Useful therapeutic hints may be obtained by looking a little more closely into its clinical history. In the first place I would lay special emphasis on the fact that the signs of failing compensation appeared suddenly, and were manifestly due to exposure to cold and wet. Up to the time of such exposure, the circulation was well maintained: decidedly better than it now is under the influence of digitalis. These two facts, viz., the sudden onset of pulmonary congestion and general anasarca, as well as the prompt improvement under treatment, prove beyond doubt that there is a great deal of healthy muscular fibre in this man's heart. If there were not, digitalis would be of little or no use, for it can no more act in the absence of muscular fibre than can an electric current traverse a divided nerve. The first requisite then to the successful employment of digitalis, is the presence of more or less healthy muscular fibre. Is there any method by which we can judge of the degree to which degeneration of cardiac muscular fibre has advanced? We are justified in referring the presence of considerable healthy fibre if the first sound is, as in health, *relatively* louder, deeper toned, and more prolonged than the second, and if the apex beat, instead of being diffuse and fluttering, is sharply defined and plainly palpable. Again, a distinct murmur can only be produced by a heart acting with considerable force, so that a faint murmur coinciding with signs of failing compensation is of more serious import than a distinct one. The response to appropriate treatment is, however, the best of all tests of the condition of the cardiac muscle.

Another indication for the employment of digitalis which was distinctly present in this case, is weakness and irregularity of the pulse. Withering, who wrote a treatise on digitalis towards the close of the last century, and who probably did more than any one else to bring the drug into judicious use, had the sagacity to perceive that it is much more efficacious when the pulse is feeble and intermittent than when it is hard and regular. Although the phrases "high and low arterial tension" were not then invented, the treatment of this keen observer was just as skilful as though they were.

The next question we have to consider is: whether the success which followed the use of digitalis in this case was due to the nature of the lesion, or, to express it in more general terms, whether the indications for the employment of digitalis in cardiac disease depend upon the valve affected and the nature of the circulatory disturbance to which it gives rise. This question has given rise to a great deal of profitless discussion, owing to the fact that most of the so-called observers have approached their cases of heart disease with preconceived opinions derived from authoritative teachers. For example, Grisolle, one of the most distinguished physicians of his time, declared digitalis to be not only useless but injurious in all such cardiac valvular lesions as give rise to stenosis. In 1867, Selion,[1] in his inaugural thesis, expresses an opinion exactly the reverse, for he says that digitalis is indicated in stenosis of the valvular orifices; contra-indicated in those which give rise to insufficiency.

In 1877 Milner Fothergill adopts the same view so far as aortic stenosis is concerned. Digitalis, says Fothergill,[2] is "useful in aortic stenosis. By exciting a more powerful ventricular contraction it enables a larger amount of blood to be driven through a narrowed orifice in an equal time, thus establishing a new equilibrium."

Niemeyer, on the other hand, held that digitalis was, as a rule, contra-indicated in aortic stenosis, and advised that in this form of heart lesion it should only be employed in cases in which compensation is failing or the action of the heart is so rapid as to prevent the proper discharge of the contents of the left ventricle.

The same differences of opinion have prevailed with reference to the use of digitalis

[1] Quoted by Huchard.
[2] *British Medical Journal*, Oct. 13, 1877.

in lesions of the mitral orifice. Niemeyer advised its use in mitral stenosis, on the ground that by slowing the action of the heart it gave the left auricle more time in which to discharge its contents into the left ventricle. On the other hand, Potain maintained that it was in just these cases of mitral stenosis that digitalis could be most easily dispensed with.

Gubler, a well-known French authority, held that both in mitral insufficiency and stenosis, little benefit was to be derived from digitalis.

These are but a tithe of the contradictory statements with reference to the best cardiac tonic in the Pharmacopœia. Can they be reconciled, and, if so, in what manner? Certainly not by endeavoring to impeach the testimony of the distinguished men I have quoted. They are all partly right, and therefore none of them entirely wrong. The cause of their discrepant statements concerning the action of digitalis is to be found in the stage of the disease in which they employed it. In the same case of valvular heart disease, digitalis may be found decidedly injurious in one stage, useless in another, and decidedly beneficial in the third. With reference to the action of digitalis, cardiac valvular disease has been divided into three stages: 1. Eusystole. 2. Hypersystole. 3. Hyposystole. In the first, compensation is fully made for the valvular defect. There is no dyspnœa except in decided exertion; no palpitation; no cough; no œdema, or any other sign of venous stasis. In such a case digitalis is not indicated; it is absolutely useless and might be injurious. The only treatment to be advised is of a strictly hygienic nature.

At a later stage of the same case the symptoms will have undergone a very decided change. The heart has enlarged; there is a tendency to active congestion, manifested by fulness in the head, cephalalgia, tinnitus aurium, vertigo and insomnia. The impulse of the heart is powerful and outside of and below its normal situation, while the pulse is full and resistant. Under such circumstances as these, digitalis is decidedly injurious, and since this stage is more pronounced in cases of aortic disease, especially aortic regurgitation, the hasty inference has been made that digitalis is injurious in all cases and stages of aortic lesion. The bromides, morphia and aconite are the drugs for this stage of valvular disease, but the most important rôle is still to be assigned to hygiene. A bland diet, of which the only animal ingredients are milk and eggs, should be prescribed, and a rigid abstinence from alcoholic liquors, tea, coffee and tobacco, enforced. The stage just described is the stage of *hypersystole.*

The stage of *hyposystole* may be said to begin when there is dyspnœa on slight exertion or even in ordinary conversation, œdema about the ankles, at first only observed at night on retiring, and a scanty secretion of urine. There will also be failure of appetite and other signs of digestive disturbance due to disordered circulation of the gastro-intestinal tract. In fact digestive disorders are so frequently prominent that cardiac dyspepsia is a well-recognized morbid condition. These symptoms coincide with diminished arterial tension; perhaps also with feebleness, irregularity and intermittence of the pulse. It is in this stage of heart disease that digitalis is employed with the most brilliant results; and as this stage may be reached in any case of heart disease, irrespective of the valve affected, it follows that the true indications for this drug are found rather in the symptoms of cardiac affections than in their physical signs.

It is undoubtedly the case that certain valvular affections are, as a rule, more benign in their course than others, and may last for years without giving rise to any symptoms, the patient finally dying of some intercurrent affection. The indications for digitalis in such cases may never arise unless, as in the case before us, exposure to cold and wet, or other depressing causes, may induce a state of acute cardiac insufficiency. The facts above mentioned afford the only satisfactory explanation of the discrepant statements with reference to the employment of digitalis in heart disease.

I trust I have made it plain that the indications for digitalis are to be found only in the functional capacity of the cardiac muscle. When it is working regularly and overcoming the valvular obstruction without exhausting the reserve force inherent in every heart, digitalis is useless and may be injurious. When the heart is excited in its action; that is, when it is making superfluous efforts to overcome the obstruction, provided this coincides with increased arterial tension, digitalis is decidedly injurious. When the arterial tension is low, and the whole circulation is approaching a venous type, digitalis is decidedly beneficial. These statements apply to all cases of heart disease,

irrespective of the particular valve or valves involved.

On prescribing digitalis in a given case and obtaining no immediate benefit from it, you should not hastily conclude that it is worthless. Although the fact is denied by some, there can, I think, be no doubt that the action of this drug is cumulative. In the case before us the daily urinary secretion on admission was fifteen ounces, and it was not until digitalis had been administered for a considerable period—about forty-eight hours—that the urine was greatly increased in amount. At the end of the period referred to, it reached the high figure of 125 ounces.

There are certain effects of digitalis which are often attributed by the inexperienced to the disease for which it is prescribed. For example, while slowing and strengthening the pulse, it often makes it very unstable, so much so that the least excitement will cause it to increase in frequency at the rate of from twenty to thirty beats per minute. The same result is produced by slight muscular exertion, such as turning over in bed. For these reasons the best results from digitalis are obtained by keeping the patient at rest while he is taking it. When the circulatory equilibrium is thoroughly restored by the use of this drug, the patient may be allowed to rise, and take a proper amount and kind of exercise.

In cardiac disease, especially when the patient is taking digitalis, the physician should never neglect to compare the number of the pulse beats with those of the heart. Cases are now and then met with in which the number of the cardiac pulsations is greater than the number of pulsations in the radial artery. This is due to the fact that some of the cardiac contractions are abortive, or if not entirely so, are too feeble to cause a palpable pulse at the wrist. The number of the heart beats may be exactly double those of the radial artery; and, according to some authorities, this is due to an asynchronous contraction of the two sides of the heart. I have published a case[1] in which, in my opinion, this condition undoubtedly existed. The possibility of the right and left ventricles acting independently of each other has been denied, and when we consider the manner in which the spiral, circular and other muscular fibres, pass from one ventricle over another without any tendinous septa, or other lines of demarcation, it seems difficult to understand how this can occur. However, in the case to which I refer, the sphygmograph recorded two beats of the heart to one of the radial pulse, and the relation of the curves representing the double heart-beats was, in point of volume, just what one would expect from the relative muscular force of the two ventricles.

I mention these peculiarities of cardiac action because they have been attributed to the action of digitalis. The question whether or not they are to be ascribed to this drug, is, in my opinion, an open one. There is one form of cardiac action which is generally agreed to be due to digitalis, and to which reference must be made, lest on observing it you should attribute it solely to the disease. It is a species of regular irregularity manifested by what has been called the "pulsus bigeminus;" that is to say, there will be two rapid beats of the pulse separated by a long interval, and this may continue for hours.

There are many other interesting points concerning the employment of digitalis in heart disease to which reference may be made in subsequent clinics.

COMMUNICATIONS.

A NEW POISON IN CHEESE.

BY VICTOR C. VAUGHAN, M. D.

During the past two or three years we have received at the Hygienic Laboratory of Michigan University a number of samples of cheese which, it was claimed, had caused nausea and vomiting in those eating of them, and in which we were unable to detect tyrotoxicon. Some of these samples produced vomiting and purging in cats and dogs to which the cheese was fed directly. Of course, the evidence that these samples had been the actual cause of the sickness among the people who had eaten of them was confirmed by the experiments upon the animals; but inasmuch as we were unable to detect the poison, we were compelled to report as follows.

"The poisonous character of the cheese has been proven by experiments upon animals, but we have failed to demonstrate the nature of the poison. Tyrotoxicon could not be detected."

One sample of this class was found by my assistant, Dr. Novy, to be very poisonous. Some of this cheese was covered with absolute alcohol, and after standing in a dish for some weeks the alcohol was allowed to evaporate, then 100 grams of the cheese was fed to a young dog and caused its death within a few hours. Sterilized milk to which a small bit of the cheese was added, after standing in the incubator at 35° C. for twenty-four hours, became so poisonous that 100 c. c. of it introduced into the stomach of a full-grown cat caused death. Dr. Novy made plate cultures from the cheese and from the spleen and liver of the dead animals, and succeeded in identifying one germ as common to both. Sterilized milk inoculated with a pure culture of this germ, and kept in the incubator, proved fatal to cats. But with the advent of cold weather the germ lost its toxicogenic properties, which were not restored by subsequent cultivation in the incubator.

In a second class of samples, the poisonous character of the cheese was not confirmed by direct feeding. Cats, rats and dogs were fed with the same quantities as above, without any appreciable effect. The report made upon the samples was as follows.

"Animals fed upon the cheese were not affected. Tyrotoxicon could not be found. The sickness in the people was probably due to some other cause."

The last sentence of this report was probably wrong, as will be shown from the following experiment. Two kilograms of a cheese of this class was extracted repeatedly with absolute alcohol. The part insoluble in alcohol was then extracted with water. The aqueous extract, after filtration, was allowed to fall slowly into three times its volume of absolute alcohol. A voluminous, flocculent precipitate resulted. After twenty-four hours the supernatant fluid was decanted, and the precipitate was dissolved in water and re-precipitated with absolute alcohol; then it was collected and speedily dried on porous plates. A small bit of this precipitate was dissolved in water; and forty drops of this solution, injected under the skin on the back of cats, produced invariably within one hour vomiting and purging. After the partial collapse which followed the vomiting and purging, and which was evidenced by the animal sitting with its chin resting on the floor, recovery gradually followed. The same amount of the solution injected into the abdominal cavity of white rats rendered the animals within ten or fifteen minutes perfectly limp, and the only evidence of life observed was rapid respiratory movements. The rats lay upon their sides, and could be handled without manifesting any attempt at movement. In this condition some died after three or four hours, while others, after lying in this position for from eighteen to twenty-four hours, gradually improved, and after some days seemed to be wholly recovered.

This substance belongs to the so-called poisonous albumins. From its aqueous solutions it is not precipitated by heat or nitric acid, singly or combined. Its solutions respond to the biuret test. It is not precipitated by saturation with sodium sulphate, nor by a current of carbonic acid gas; therefore, it is not a globulin. It is precipitated by saturation with ammonium sulphate; and this fact removes it from the peptones.

That animals were not affected when fed with the whole cheese may be explained by the supposition that they did not in this manner get enough of the poison to affect them. It cannot be said positively that the samples of cheese of the first class mentioned above owe their poisonous properties to this substance. We have not had the opportunity of testing samples of this class since the recognition of the poisonous albumin in those of the second class. Four samples of the latter have been tested for the poisonous albumin with positive results.

It may be found that traces of this poison exist in all samples of green cheese. This point will be investigated.

It is highly probable that the poisonous effects of some samples of sausage and meat are due to similar products of bacterial activity.

FRACTURE THROUGH THE ANATOMICAL NECK OF BOTH HUMERI.

BY WM. C. TODD, M. D.,
ROXBOROUGH, PHILADELPHIA.

I am induced to report the following case from the extreme rarity of such an injury. I was called in consultation by Dr. S. C. Ingraham, of Wissahickon, in the case of a woman of advanced years, who had had a fall down a cellar stairway, by which both

shoulders were severely injured. The arms were rendered useless, there was severe pain in the region of both shoulder-joints, with some swelling but no apparent shortening or displacement. Distinct crepitus at both joints could be plainly felt on grasping the joint tightly with one hand and making slight movement of the arm with the other. Both arms were carefully bandaged from the fingers up; well-padded metallic splints were fitted to the upper part of the humerus and shoulder, and secured by bandages; flat pads were placed in the axillæ; and the arms were secured to the sides from the shoulders to the elbows, with slings to support the hands and forearms.

The bandages were changed once a week, when the parts were carefully bathed and dried, and precautions were taken to prevent chafing. At first the patient was confined to bed on her back, but afterwards, in the daytime, she used an easy, reclining chair. In six weeks the splints and bandages were removed, and it was found (contrary to our expectation) that union had taken place with fair motion, which we expect to improve in time. Some thickening remains around the heads of the bones, which may possibly be absorbed. The arms were again placed in slings, with directions to gradually resume their use.

There may have been some predisposing cause in this case; but none was apparent, except the age of the patient, who had never suffered before from fracture.

THE DISEASE OF INEBRIETY.

BY T. D. CROTHERS, M. D.,

SUPERINTENDENT WALNUT LODGE HOSPITAL, HARTFORD, CONN.

It is a curious fact that, notwithstanding all the clinical evidence so easily obtained in the practice of every physician, the disease of inebriety is still denied and doubted by many persons. This is natural in a certain class of physicians, who are always averse to any change of present theories and beliefs, because it requires mental changes and efforts to readjust themselves to new states and conditions. But the medical man who is reckless enough to defend his views in print always reflects his own knowledge of the subject more than the opinions of others. Recently such a man considered it his duty to contradict the fact of disease in inebriety, and to show its absurdity and its conflict with the teachings of the Bible and other experience, citing as authority (which seemed to him conclusive) the opinions of the late Dr. Gray, of Utica, and Dr. Bucknil, of London. Feeling that he had fully established his view of the topic, he gave way to sarcastic strictures upon me and others engaged in the same work, and finally closed with a record of two cases, which to him seemed conclusive. One of these cases came under my care, and thus enabled me to compare the evidence on which he based his denial of the disease of inebriety.

The history of the case, as he described it, was briefly as follows. A. B., a merchant, thirty-four years old, had drank to excess for ten years, had lost his property and was a pauper living on the charities of his friends. He had Christian parents and excellent training, and had been successful in business. He had begun to drink wilfully at first, and continued, notwithstanding all advice and persuasions of his friends. He would promise and pledge himself to abstain, then deliberately plan and determine a drink period, and in the most cunning way deceive his friends. When prevented from going away, or when restrained by the presence of some one, he would abstain for a time; but with the first favorable opportunity he would drink to great excess. The insane-like cunning and methods to procure spirits, while apparently deploring his condition and affirming that he would stop, but making no effort to do so, was proof of vice and immorality, and in no possible way could it be called disease.

A more careful examination showed that A. B.'s grandfather was a periodical inebriate, that one uncle was insane, and that his father suffered from attacks of melancholy at intervals, and his mother was a pronounced neurotic. From early life the patient had periods of insomnia and was always untruthful and unable to concentrate his mind on one thing long. He probably drank at first to keep up in business, and afterwards drank according to time and opportunity. He inherited a neurotic diathesis and a special tendency to exhaustion, for which alcohol was a most grateful means of relief. He was also of defective brain organization and was unstable, emotional and childish in his methods of deception. He would agree to any theory that explained his conduct and join in any methods and plans

for his relief, and at the same time carry on an intrigue to procure and use spirits. On one occasion he partook of the sacrament, as a most devout convert, and that night broke into the church and stole the wine that remained and drank it in his room. He was clearly a reasoning maniac of the alcoholic type and died of some unknown brain trouble.

The second example used to illustrate the vice of inebriety was a solitary midnight drinker of the dipsomania type, who at intervals retired to some obscure hotel or boarding-house, and drank to stupor at night for a week, then returned and manifested great activity in the temperance cause. At other times he would refuse to see any one in his room at night for days, then come out, giving as an excuse that he was engaged on some literary work. This man was found dead in his room, with many empty spirit bottles about him.

The inebriate, like the insane, always denies that his habit is the result of disease, and insists that he can stop at any time, and when he fails to do so ascribes the failure to some trifling condition of the surroundings. To many superficial observers the statements of such persons are accepted as facts, no matter how much they are contradicted by clinical history. In a noted contested will case, the testator was an extreme prohibitionist and a radical temperance man. He denounced every scientific effort to study these cases as fallacious and mercenary; and yet he was an inebriate and drank in secret. When the drink craze came on he had urgent business in New York city, and would be away a week or more concealed. After one of these unexplained absences, he wrote his will, which was contested, and the fact of his secret drinking came out. A review of his history revealed many very clear indications of disease, in his intemperate life and conduct. He had been implicated in several very unusual transactions, and at times was extremely miserly, or lavishly generous. He often displayed great extremes of conduct and character, and had been under treatment for years for nervous dyspepsia. At one time he was under arrest for setting fire to a saloon. As he was very bitter and vindictive against any one who drank, or sustained the saloon influence, no doubt he was guilty. His mental soundness was certainly questionable for many years, and the will was written after an attack of secret drinking, when his mind was more than usually disturbed; yet the will was sustained.

In a recent case, the disease of inebriety appeared, although it was not recognized, and it has been the subject of much comment. A quiet, studious physician, who was very generous and popular with all his patrons and associates, served one term as a legislator. From this time a total change of character and disposition began. Before this he was an occasional moderate user of spirits, now he drank to excess at intervals, was slanderous, untruthful, intriguing, and irritable. For a period of ten years up to his death, he was a centre of contention, and often committed the most disreputable acts. He was a low politician, and drank to excess at times. At his death, the executors refused to pay certain unusual contracts, on the ground that at the time the contract was made, he was unsound and incapable. The evidence of disease, from the sudden change of his conduct, character and disposition, associated with the excessive use of spirits, was not recognized by the court and jury, and the expert witnesses for the defense were treated as dishonest and culpable, for assuming that such a man was not sound and responsible.

It is difficult to understand on what basis the disease of inebriety is doubted, in the increasing army of cases in which spirits are used constantly, or to great excess at intervals, associated with marked changes of character and conduct. Any other interpretation of these groups of symptoms than that of brain failure and degeneration seems nonsense. The best authorities all agree, that the life and functions of the highest cerebral centres are always disordered by interruption in their natural nutrition. If the blood is impoverished, or poisoned by any deleterious substances, the effects are visible in all the brain functions. No one can use spirits continuously or in excess without breaking up the normal qualities of the blood and impoverishing the brain. No man can use spirits to excess and have a healthy, sound brain; and changed conduct and character are unmistakable symptoms of this. The facts in this field are within the observation of every physician, and are not theories but can be demonstrated beyond all doubt or question.

What is most needed is clinical study and medical observation of these cases above all moral theories, or present conceptions of what inebriety is or is not.

TREATMENT OF SCIATICA WITH PHOSPHORUS.

BY A. K. BELL, M. D.,
MADISON, GA.

One of the most unpleasant feelings an honest doctor can experience, is created when he sees his patients continue to suffer pain while he is unable to give them the desired relief. Such is often the case when one treats sciatica; but I have now treated three severe cases with such marked relief that I have no hesitancy in recommending to my fellow-practitioners the elixir of phosphorus, which has served me so well.

Case 1. A negro man about forty years old, who had always been quite well, began to suffer. The pain came on gradually, beginning in the gluteal region, and running down the posterior portion of the leg. In two or three weeks from the first symptoms he was so much crippled that he was compelled to go to bed. He had been treated about one month by two physicians before I saw him. In two weeks of treatment I gave him many things, including morphia and atropia combined and separate, with the result of only a few hours of relief. After the effects wore off he would suffer as intense pain as before. After about two weeks of such treatment I gave him elixir of phosphorus. In a few days after the beginning of this treatment he rested better at night from pain, and in one more week he was dismissed as cured. One year afterwards he had another attack which yielded at once to the treatment with phosphorus alone.

Case 2. A white woman, forty-two years old, suffered three months with severe pain from the gluteal region down the posterior portion of the leg. She was under treatment all the time, and all the remedies common to the cure of sciatica were used; but her only relief from pain was gained by using morphia. I was called to see her, and at once ordered the elixir of phosphorus, using nothing else. In one week the woman began to improve, and in another week she was dismissed. She is my next door neighbor, and I have not heard of her complaining since.

Case 3. A mulatto woman, about forty years old, began to suffer similar to the others one year ago. She was confined to the bed and had been under treatment for six weeks; had taken no anodyne, and had suffered intense pain all the time. When I first saw her, she could not turn herself in bed. I gave her morphia and atrophia combined, to relieve the pain. She was very anemic and emaciated. I ordered tartrate of iron and potash for one week, when she gained color and strength. Then I gave the phosphorus, and in two weeks she was up and walking about.

I cannot believe these are *post hoc*, but *propter hoc* cases. I hope others will try this preparation, and should they or should they not have the same good results as I, I would be glad to hear from them.

FOREIGN CORRESPONDENCE.

LETTER FROM BERLIN.

BERLIN, October 11, 1890.

The Royal Friedrich-Wilhelm University.—The Royal Military Medical Institute.—The City's Provisions for Accidents and Fires —Influenza Statistics in the Prussian Army.—Treatment of Delirium Tremens.—Syphilis in the Horse.—A Boom for Emphysematous Patients. — A Button Lodged in the Nose Three and One-half Years.—Spermine.

The first question usually asked by an American visiting Germany to perfect his scientific education, is: "Where is the University?" Imagine his surprise when he finds, even in a world-renowned university-town like Gœttingen, that this question cannot be answered without great difficulty, if at all. The fact is that there usually exists no imposing array of connected structures forming the University, as is the case in America, but that the German Alma Mater is made up of a half a dozen or more "Institutes," scattered all over town, which in their entity represent the University. And frequently these institutes, especially those of recent date, such as the Hygienic and Bacteriological Institutes, are magnificent structures, while the central university building is often insignificant. This is signally the case in Berlin. The University Unter den Linden, *vis-à-vis* the palace of the late Kaiser Wilhelm, is an unworthy exponent of its fame and honor. It may be interesting to learn of some of its history. It was in the year 1807, the battle of Jena had just been lost and the Prussian kingdom was

practically extinguished by the terrific blows of the Corsican usurper. But the high-minded Prussian king, Frederick William III (the father of old Emperor William), far from believing in the permanent decline of the star of the Hohenzollerns, was first to regain heart, and publicly declared: "We have lost our material possessions, so we must try to strengthen and concentrate our spiritual ones; and, in this sense, I order the founding of the University of Berlin." Six years later the noble king had the satisfaction to reap the fruits of his seed. The yoke of the French tyrant was thrown off through the incessant stimulation of Prussia's youth by men like Roerner, Arndt, Jahn and Fichte, who taught at the new University. You know well what the University of Berlin represents in our day. Allow me to quote just a few names of the Medical Department: Graefe, Traube, Frerichs, Langenbeck, Schroeder are no more, but Virchow, Koch, Hoffmann, Helmholz, Dubois-Raymond, Liebreich, Leyden, Gerhardt, Henoch and Bergmann still grace the faculty, under whose auspices a most successful International Congress has just been held.

The great Central Institute where the medical student receives his entire clinical education, the Royal Charité, does by no means come up to the requisites of the day. The lecture rooms of Gerhardt and Henoch, which are frequently attended by 300 students, hold comfortably about one-third of that number, and late comers are happy enough to catch a word here and there, not to speak of seeing teacher or patient. The Institutes devoted to Physiology, Pharmacy, Chemistry, Anatomy and the Surgical and Gynecological Hospitals are magnificent new structures, while those of Hygiene, Pathology and particularly Chemistry are confined to miserable quarters. The height of shabbiness, however, is undoubtedly reached by the University Unter den Linden. You enter by the main gate and find yourselves immediately surrounded by impenetrable darkness. Long, but exceedingly narrow corridors lead from one wing to another. The walls are covered with bills, official and other ones, but the miserable light shed by the parsimonous lamps—old Sol has never matriculated at the Berlin University—forbids their perusal even to such students as should accidentally be free from myopia. The rooms are ridiculously small and primitive, the auditorium maximum on the second floor being the only room reminding you of the august character of the institution. The most ludicrous thing belonging to the University is its big clock. It hangs freely in the front hallway and between the two main entrances which oppose each other. But only those entering by one gate are blessed by reading off its time, the students who come in the other way see merely a circular piece of pasteboard. But old and rickety as the building is, which was originally a mansion occupied by Prince Ferdinand, of Prussia, it has many good things attached to it. In the first place its lovely location, Unter den Linden, where all that lends life and soul to Berlin—royalty, soldiers and the upper ten thousand—are ever visible. At one o'clock the ever-fascinating event known as "guard-mount" takes place. A company of a daily-changing regiment parades with the full band of the Regiment the Linden and relieves under various interesting military manœuvres, the company doing duty on the guard-house, just adjoining the University. The scene is never missed by the students and the big building becomes vacated when the roll of the drum and sound of the fife announce the soldiers' approach. A lovely garden surrounds the institution on either side, a part of which contains rare medicinal trees and plants, all clearly labelled for the use and instruction of the students. A "Reading Hall" is also located in the garden; and the Royal and University Libraries are in the immediate neighborhood. As an oddity I will mention that an old privilege of the University allows its janitor to keep and sell beer, which he does of course, but no case of intoxication has ever been reported.

In some future letter I shall speak in detail of the various Institutes of the University, and will now only mention a few points in regard to the Military Medical Institute.

The Government in Germany provides well for the sons of officers and military surgeons. The former are placed in the "House of Cadets" and are educated as officers, while the latter are placed in the Military Medical Academy, which provides the entire army with surgeons. All assistants of the Charité are taken from the Military Medical Academy, a fact which is causing a good deal of dissatisfaction among the rest of medical men. But as the Charité is a Royal Institution grumbling is of no avail.

As far as official or municipal help in accidents is concerned, there is no large city

on the globe worse provided for than Berlin. A Hospital Ambulance Service, such as is doing excellent work in America, is unknown here. A few accidents happening here of late have at last opened the eyes of the community. Several fires broke out at night, and as a result a number of persons perished who, if medical aid had been sooner obtainable, might have been saved. I will say a word too about the Berlin Fire Company. According to its own estimate the "Berliner Feuerwehr" is an unrivaled institution; but according to my judgment it is far inferior to the fire companies in New York, Philadelphia and all other large towns in America. You never know whether they are returning from a fire or hurrying to one, for they proceed with a never varying slowness. Besides, as became evident in the recent accidents mentioned, the single men are machines only and are not allowed to follow their own and often fortunate ideas. They are drilled as soldiers and consequently are poor mediums for saving human life. True, Germany consists of soldiers only, everything else is of secondary importance.

The statistics of the Military Medical authorities on the great epidemic of influenza, just published, present many points of interest chiefly from the etiological point of view.

The observations made in the German army pertain to 55,263 cases. In many instances the infection could be traced directly. For example, the garrison of Pasewalk, a town located near Berlin, had remained free from the affection until a captain of a Berlin regiment was ordered to do duty in Pasewalk. The captain was the first victim of influenza, next in order came the military surgeon who treated him, then a sergeant whom the captain had ordered to report, next came wife and children of the surgeon, and a friend of the captain. In a few days the entire town had the influenza. In 254 cases persisting neuralgia, and in 290 cases inflammation of the middle ear was found. Sixty cases terminated fatally.

At the recent meeting of German Naturalists and Physicians, held at Bremen, Dr. Aufrecht, the well-known clinician of the Magdeburg City Hospital, discussed the treatment of delirium tremens. Two main questions, he said, come up for consideration, viz.: Have we a sovereign remedy for delirium tremens? and, does the patient need alcohol during the treatment? Aufrecht declared that he had never obtained beneficial results from the use of opium and morphine, and that he relied exclusively on hydrate of chloral. He usually prescribes in the evening a drachm of the drug to be taken in half an ounce of simple syrup and syrup of orange peel each. Later on the dose can be increased. In all uncomplicated cases, alcohol cannot be dispensed with. He gives usually daily half a pint of Hungarian wine or the following potion:

℞ Alcoholis (90 per cent.) . . . . . f℥ii
Syr. simpl. . . . . f℥ii
Tr. aromaticæ
Tr. amaræ . . . . . āā gtt xv
Ag. amygd. amaræ . . . . . f℥ss
Aq. destillat. . . . . f℥viii
M. S. Tablespoonful every 3 hours.

Aufrecht has treated in all 294 simple cases. Ten patients died (four of these received half a drachm of alcohol and one-third grain morphine every night. Of 124 cases treated with hydrate of chloral not a single one was lost. Dr. Noele, of Osnabrueck, on the other hand, was opposed to the exhibition of hydrate of chloral or alcohol, and emphasized the gratifying results he had obtained from warm baths extending over fifteen minutes and followed by the cold douche.

Recent experiments made by Dr. Lesin to ascertain whether syphilis can be communicated to a horse, have been clearly successful. The horse bore the injections and inoculations with syphilitic substance exceedingly well, and on dissection showed numerous proofs of syphilitic infection, such as swelling of the lymphatic glands and plaques near the semilunar valves of the aorta and in the pulmonary artery.

Dr. Steinhoff, of Berlin, has just completed an apparatus which appears of great value to emphysematous patients. The exceedingly costly Pneumatic Cabinet, though valuable in the treatment of the catarrhal symptoms of emphysematous patients, has nevertheless proved useless in the treatment of the disease itself. Prof. Gerhardt, of the Berlin University, has first called attention to the high value of manual pressure upon the thorax on expiration. Unfortunately no one, neither patient nor nurse, can keep up such pressure for longer than fifteen minutes. An emphysematous mechanic by the name of Zoberlin perfected some time ago —under guidance of Prof. Rossbach — a chair which assists the patient in compressing his own thorax. But as emphysematous

patients are easily tired and abhor continuous exercise, Zoberlin's ingenious apparatus could not universally be utilized. The invention of Dr. Steinhoff is a "respiratory belt" filled with compressed air, which is made to compress the thorax on expiration. A desk-like piece of furniture contains the various accumulators, a small dynamo or gas motor doing the work. In seven cases the belt brought relief.

Berlin surgeons extracted recently from the nose of a girl, seven years of age, a button which had lodged in that part for 3½ years. The chief symptoms produced by the foreign body were chronic coryza, snoring breathing, dyspnœa and nasal speech, all of which receded promptly after extraction of the button.

As the testicle emulsion used by Prof. Brown-Séquard does not exclude the possibility of septic infection, various observers have recently aimed at isolating the active principle of the alleged invigorating substance contained in that organ. Prof. Roehl appears first to have been successful in this attempt. He has prepared the substance from the testicles and prostatic gland of young, healthy oxen and stallions. Spermine—that is the name of the active principle in question—is precipitated by chloride of gold, and on treatment with metallic magnesium gives off the odor of fresh human sperma. Dr. Roschtschinin, private physician to the Russian Emperor, extols the invigorating and almost marvellous power of the remedy in asthma, paralysis of the extremities, diabetes, delirium tremens and tuberculosis. He uses spermine in a one or two per cent. sterilized solution, of which he administers one syringeful subcutaneously. The solution is kept in glass tubes, and the syringe is to be cleaned before use with concentrated carbolic acid. Spermine contains about eighteen per cent. of peptone.

PERISCOPE.

Simple Method for Controlling Epistaxis.

Dr. W. W. Parker, of Richmond, Va., says, in the New York *Medical Record*, October 4, 1890: The plan of arresting hemorrhage from the nose, which I here describe, I have used for thirty years without one failure. When I first began to practice I used Bellocq's instrument, but I found it painful, and, in small children, exceedingly troublesome of application. Two months ago a man twenty-three years old, in this city, was operated upon for irregular septum (a small part of the bone was removed), which was followed by troublesome hemorrhage. The operation was by a very skilful specialist, who, upon application of the patient the day after the operation, plugged the posterior nares with difficulty. But the hemorrhage persisted for three days, when the patient, whose father's family I had attended for many years, applied to me in company with his father. I, of course, declined to have anything to do with the case, and urged him to return at once to the specialist who could do everything that was necessary. This he postively refused to do, and said if I would not attend him he would get some one else. He had visited the doctor three times, but the bleeding continued. As it was ten o'clock at night when he came to my office, I told him I would stop the bleeding and would see his doctor next morning and get him to call at the patient's house. This I did. I stopped the bleeding at once, but kept the patient and his father in my office till twelve o'clock at night to see if the hemorrhage really was arrested. This was the last of the bleeding. This man was of a hemorrhagic diathesis, and some three weeks after this, he had hemorrhages from the lungs, which has continued occasionally up to this date. At the Red Sulphur Springs of Virginia he gained twenty pounds but the bleeding from the lungs continued. He is of a phthisical family. I have been thus particular so that I might satisfy the reader that this was a bad case of epistaxis.

My plan is not only effectual, but is easy of application and absolutely painless, and can be probed in the smallest patients. The little device which I use is made of fifteen of the long threads of patent lint, size three and one-half or four inches long, which I double on themselves and tie in the middle, and let one end of the string be six or eight inches long so as to pull the plug out when necessary. When doubled on itself it looks like a "comet" in miniature with a nucleus and thirty tails (or twice the number of threads used). A probe, or soft piece of pine but little bigger than a match, is pressed up against the centre, and it is passed back upon the floor of the nasal cavity and pushed on till you reach the posterior nares. This will be known both by the resistance and the length of the probe, or the depth which

you have reached. Then slowly withdraw the probe and plug the anterior nares and you have arrested the bleeding. These twenty or thirty ends floating in the blood at once coagulate it. The passage of the soft lint gives no pain whatever. In persuading children to submit to the operation, I often pass the lint up my own nose to satisfy them it gives no pain. If lint is not at hand I use the largest size spool cotton.

Some years ago I called the attention of one of our local societies to this matter, and it was mentioned in a local journal, but attracted no attention. Seeing the notice of Dr. Fridenberg's method in the *Medical Record*, I send this to you hoping it will have a wider circulation. Any sensible layman can perform this operation. Many years ago I was wont sometimes to remain at the patient's house for hours, fearing a return of the bleeding, but do so no longer. The plug is removed in from twenty-four to forty-eight hours. It gives no pain and the patient is willing for it to remain. The other methods are all painful in execution, and the discomfort, while the plug remains, is very considerable.

Chlorodyne Poisoning.

The *Lancet*, September 27, 1890, contains the following account of a case of poisoning by chlorodyne, under the care of Dr. Dickinson, in the Liverpool Northern Hospital, in which it was estimated that there were sixteen grains of morphia in the quantity taken. A stout, flabby man, fifty years old, was admitted to the Liverpool Northern Hospital at 4 P. M. Two hours previously, when under the influence of alcohol, he had taken the contents of a four-ounce bottle of chlorodyne, equal to sixteen grains of morphia. On admission he was livid and comatose, respiration short, stertorous, and at long intervals, pulse slow and full, and pupils contracted. Zinc zulphate and apomorphia had been given without effect. A stiff tube was at once passed, and the stomach well washed out by the syphon. Some hot coffee was then introduced by the same channel. A powerful Faradaic current was then applied and soon had the effect of partially rousing him and improving respiration and color; but as soon as this was discontinued lividity returned. Mustard plasters were applied to the chest and soles of the feet. After a time the battery appeared to lose its effect, but smacking the chest was of good service. As he did not improve the cold douche was applied to his face, with instantaneous effect, and he was soon able to be propped up with his feet over the edge of the bed. As the douche was found inconvenient of application in this position, a Higginson's syringe was used and cold water squirted at intervals on to his mouth and nostrils. This seemed to annoy him much. He was persuaded to stand up and to try to walk, but after a dozen steps would relapse into unconsciousness and lividity. The same result would follow any intermission of stimulation for more than a few seconds. Several hypodermic injections of atrophine, ether and strychnia were given between 4 and 8 P. M.; also sal volatile by the mouth. At about 8 P. M. he became more sensible, and could give an account of his mishap. From this time, although constantly dropping off to sleep, he could easily be aroused. He was kept awake, walking a little at intervals, till 6 A. M., when he was allowed to go to bed. At 11 A. M. he walked out of the hospital perfectly well.

Commenting on this case, Mr. Mothersole said he would like to make a few remarks as to the treatment of this and similar cases. Apart from the administration of physiological antidotes, its *rationale* is to maintain respiration and circulation until the effects of the poison pass off. This is best attained by means calculated to restore consciousness; in the case described it was remarkable how the patient's respiration and color improved whenever he showed any sign of sensibility. The prospect of saving life depends mainly upon the stock of irritability at our command and the means we possess of exciting it. It is desirable to have a variety of stimuli, so as to alternate them, in order that their effects may be less likely to wear off. They should not be applied more vigorously than necessary, lest irritability be exhausted. At the same time internal stimulants are valuable in maintaining and increasing irritability. A most potent stimulus, and one always ready at hand, is the cold douche. The method of its application is worth attention. A large volume of water is by no means necessary. The force and suddenness of the jet and the locality to which it is applied are of far more importance. For efficiency and convenience a Higginson's syringe is an excellent weapon. And the most responsive places are the mouth and nostrils. It is almost

universally recommended that these cases should be treated by walking them about. He said he might be pardoned for holding rather strong opinions on the subject since seeing the disgusting spectacle of a patient, whose legs were utterly unable to support him, dragged about between two stalwart men. What is the object of this treatment? It depends, no doubt, on the fact that so long as the patient is able to walk about he is in no danger of dying, for he must be more or less conscious. But does this movement give much assistance in maintaining consciousness? How often does the patient, as in the case described, relapse into insensibility while being "walked about," even when the contact of his feet with the ground derives an additional potency from the presence of mustard plasters on his soles? In cases of real danger the act of walking affords little if any stimulus, and it must be terribly exhausting when kept up for any length of time. In this way it may help to account for some cases of relapse and death. It is far better to keep the patient sitting in a chair, consciousness being maintained by repeated irritation. In the worst cases the endeavor should be made to keep the patient alive by artificial respiration.

Suturing Extensor Tendons of the Finger.

Dr. W. M. Alrich, in the *University Medical Magazine*, October, 1890, describes the case of a man 21 years old, who came to the University of Pennsylvania Hospital on June 5, 1890, with three ragged lacerated wounds on the dorsum of the right hand, caused by being caught in a planing machine. He was bleeding very profusely, having cut most of the superficial veins. It was at once noticeable that the index finger remained flexed while the others were extended. Examination showed that the tendons of the extensor communis digitorum and extensor indicis muscles were completely severed. After the bleeding vessels were secured and the parts cleaned, the distal ends of the tendons were seen at the bottom of one of the wounds while the proximal tendons were not visible. A grooved director was inserted in the tendinous canal and a counter opening made a short distance anterior to the annular ligament. At the bottom of the incision were found the proximal ends. These were secured by a pair of forceps. Another pair was then inserted in the original wound and along the canal where the grooved director had been carried, the divided tendons were drawn down, and their continuity was restored by means of catgut sutures. The tension was quite marked, since retraction had separated the divided ends about two and one-half inches. The external wounds were approximated by means of silkworm-gut, dressed antiseptically, and motion was prevented by means of a splint.

The stitches in the external wounds were removed in about five days. The patient made an excellent recovery and had perfect control of his index finger, its movements being absolutely normal.

Spermatozoa in the Urine of Women.

The Paris correspondent of the *Pharmaceutical Era*, October 1, 1890, says that a delicate point of ethics was recently raised at Bordeaux. A pharmacist of the place, having been requested to analyze a woman's urine, found it on microscopical examination to contain quite a number of spermatozoa. Feeling doubtful as to whether he should mention the fact in his report, he asked Professor P. Carles, of the Bordeaux School of Pharmacy, for his opinion on the subject. The professor replied that, not long since, he found himself in just the same predicament. A gentleman of some standing in society, who was in the habit of having his urine occasionally examined, one day sent a specimen of his wife's water, with a request that it be analyzed. The microscope having shown the presence of spermatozoa in an otherwise normal urine, Mr. Carles asked himself whether the husband, aware of the microscope's power, was not trying to verify some dark suspicions. Although such hardly seemed to be the case, the professor concluded to keep silent on his discovery. And since then whenever females' urines are presented, either described as such, or identified from special histological constituents, he has made it a rule to omit in his report all mention of any spermatozoa that may have been found. Their presence is only noted, confidentially, when the report is to be handed personally to the physician. Of course in a legal case the same course would have to be followed. The writer of the letter adds that it may be of some interest here to remark that some

years since a like instance occurred in Brooklyn, N. Y. Two well-known physicians attending the young unmarried daughter of one of the "first families" there, were one day taken aback by the discovery of swarms of the tell-tale microzoa where they had no business to be. After consultation, spermatozoa not being a morbid symptom in female urine, they wisely came to the same conclusion as the French professor, and kept their find to themselves.

Influence of Ventilation on Micro-organisms Suspended in the Air.

In a communication to the *Zeitschrift für Hygiene*, Band vii, Heft 1, 1889, R. Stern says that from ventilation we expect to get rid, not only of the gas-forming products of tissue change and of decomposition, but also —and what from hygienic considerations is still more important—of any possible bearers of infection which may be suspended in the air. His experiments show that ordinary ventilation does not fulfil these requirements. In a large room of 85 cubic meters he scattered dust containing artificially-developed bacteria. The rapidity with which the dust spontaneously settled, and the influence of different degrees of ventilation, was then tested. The quantity of germs floating in the air was ascertained each time before and after the experiment, by means of the method of Petri. When the air is quiet the germs sink quickly to the ground. On examining the fine dust collected from school-rooms, six feet above the ground, on desks, etc., the air in one and one-half hours was already found nearly free from germs. The most customary degree of ventilation, which corresponds with a renewal of the air once, twice or thrice in the hour, purifies the air of germs no more, or very little more, quickly than simply allowing them to settle. An increase of the degree of ventilation, which is scarcely feasible without causing direct draught, increases gradually the influence of ventilation upon the germs floating in the air. The limit at which a more powerful and more rapid action begins, should correspond to a renewal of the air six or seven times an hour. A rapid and complete clearing of the germs from a dwelling-room is accomplished only by a powerful draught. A considerable separation of germs from floors, paper, furniture, clothing, etc., cannot be accomplished even by strong airing of the room. Finally, the development of vapor does not quickly and completely precipitate germs suspended in the air, though it hastens their deposition in a slight measure.—*Münchener med. Wochenschrift*, Sept. 16, 1890.

Thiol.

Prof. Schwimmer, in the *Wiener medicinische Wochenschrift*, No. 30, 1890 (*Deutsche medizinal-Zeitung*, Sept. 22, 1890), states that in an endeavor to produce an artificial ichthyol, free from the unpleasant qualities of the natural article, Dr. Jacobson discovered thiol, a carbon compound, containing twelve per cent. of sulphur, readily soluble and absorbable, having reducing properties and possessing a not-disagreeable odor. The usefulness of both ichthyol and thiol is largely dependent upon this sulphur, the intimate association of which with carbon removes the irritating quality of free sulphur. Schwimmer has used thiol in a large number of cases of cutaneous disease and arrives at the conclusion that the remedy is indicated in affections in which desiccation and contraction are sought. The following are useful formulæ:

℞ Thioli liquidi . . . . . 30 to 50 parts
Aquæ destillatæ. . . . . 100 "
M. S. For topical application.

℞ Thioli liquidi
Glycerini . . . . . āā 50 parts
Aquæ destillatæ . . . . . 100 "
M. S. For topical application.

℞ Thioli liquidi . . . . . 10 parts
Unguenti simplicis . . . . . 50 "
M. Ft. Unguentum.
S. For topical application

℞ Thioli sicci pulveris q. s.
S. Dusting powder.

Buzzi prescribes gr. ss. to gr. xv of dry thiol, in tablet or pill, or gtt. iij to gtt. xx of liquid thiol, in water, three times daily.

Chicago Pasteur Institute.

Dr. A. Lagorio writes to the *Medical Standard*, October, 1890, that since the inauguration of the Pasteur Institute in Chicago, on July 2 there have been treated to date [date not stated. Ed. Reporter] twenty-four persons; thirteen having been

admitted in July and eleven in August. Sixteen were males and eight females. The youngest patient was four years old and the oldest fifty-five years. Sixteen came from Illinois, two from Indiana, one from Ohio, three from Iowa, one from South Dakota, one from Arizona. One patient was bitten by a skunk, two patients by a cat, and twenty-one by dogs. Eight patients were bitten on the hands, two on the face and fourteen on the body and limbs. Twelve patients were bitten by animals recognized to have been mad by the symptoms shown during life, and twelve patients by animals suspected of having been mad. Eight patients had their wounds cauterized with lunar caustic, three with carbolic acid, one with potassic hydrate, one with ammonia, and eleven were not cauterized. To nine patients was given the simple treatment of ten days' duration, with one inoculation daily. To fifteen patients the modified intensive treatment of fifteen days' duration, with two inoculations daily, rest on the sixth and twelfth day.

Once the brain of a suspected animal was brought to the Institute and two rabbits were inoculated with it, but the result being negative the patient was not treated. Over sixty persons were declined treatment as reasonable evidence was not produced to show that the animals were mad or even suspected to be so. Every patient tolerated the inoculation perfectly well.

The time which elapsed between the date of the bite and commencement of treatment was as follows :

1 day in 3 patients.
2 days in 3 patients.
3 days in 3 patients.
4 days in 4 patients.
5 days in 1 patient.
6 days in 2 patients.
7 days in 1 patient.
9 days in 2 patients.
12 days in 1 patient.
3 weeks in 1 patients.
1 month in 2 patients.
1 year 2 months and 14 days in 1 patient.

Not a single accident has occurred in any patient during treatment, and all left the Institute in perfect good health..

Training Schools for Nurses in New York.

From "The Training of a Nurse," by Mrs. Frederick Rhinelander Jones, in an article in *Scribner's Magazine*, November, 1890, says that the Bellevue Training School for Nurses was started on May 1, 1873, with a superintendent and five nurses, having five wards under their care.

In 1890 the school has 62 pupils and has graduated 345, while as a direct outgrowth of that modest beginning there are three other great schools in New York alone. These are the New York City, which has 64 pupils and has graduated 263; the New York Hospital, with 48 pupils and 192 graduates; and Mount Sinai, with 50 pupils and 111 graduates. There are also smaller schools in the city, but, great or small, Bellevue must always be honored as the pioneer. Her graduates are at the head of most of the important schools and hospitals in the country, and have even gone so far afield as England, Italy, and China.

The next school to be established was the New York City, which was started by the Commissioners of Charities and Correction in 1877, and is entirely supported by the City. Until last year it was known as the Charity Hospital School, because it began there, but as it grew its work spread until the old name was misleading and had to be changed. It is now the largest and in some respects the most important of all the schools, as it nurses five different hospitals—Charity and Maternity on Blackwell's Island, the Infants' Hospital on Randall's Island, Gouverneur at Gouverneur Slip, and Harlem, at the foot of East 120th Street, the last two being accident or emergency hospitals, while at Charity the cases are largely chronic. Besides the pupils of the school there are thirty-two permanent trained nurses at Charity and Randall's Island, making nearly a hundred in all, for whom the superintendent is directly responsible, and over whom she has full authority. The other schools in the city are supported from the funds of the hospitals which they nurse.

Coffee as a Disinfectant.

The *Deutsche Medizinal-Zeitung* for September 22, 1890, quotes the following from the *Journal de Médecine d'Algérie*. On an extremely hot day in Algiers, Dr. Barbier and some officers were directed to a village inn, to make an examination of the body of a murdered man. They were led to a small apartment in which the body lay, but were met by so intolerable an atmosphere that they at once retreated. Upon request a plate of ground coffee was brought and sprinkled upon the cadaver, the floor and the walls. The horrible stench disap-

peared and the examination was proceeded with without interruption. Gratified with the result, Barbier soon found occasion to make a similar use of coffee, with equal success, in the case of a body which had lain in the water for a week. He now began to use coffee in this way in the treatment of foul ulcers, and with good results. He considers coffee an antagonist of the narcotic effects of tobacco, for which there is no better antidote. He also recommends the use of coffee for the disagreeable odor sometimes acquired by ice-chests for the preservation of animal foods. To preserve game, this shouid be first cleaned and then strewn with coffee. It was also observed that cholera bacilli and other microbes lose the faculty of multiplication in infusions of coffee.

Hypnotism in Belgium.

The *Deutsche Medizinal-Zeitung*, Sept. 22, 1890, makes the *Bull. Med.* No. 60, 1890, authority for the statement that the Belgian Chamber of Deputies has recently adopted the following law:

1. Any one exhibiting a hypnotized person will be punished with imprisonment for from fourteen days to three months, and a fine of from twenty-six to one thousand francs.

2. Any one not medically qualified who shall hypnotize a person under eighteen years of age or a person not of sound mind, shall be punished with imprisonment for from fourteen days to one year and a fine of from twenty-six to one thousand francs, even though the hypnotized person be not used for exhibition.

3. Any one who, with fraudulent intention or with intent to injure, shall permit a hypnotized person to write or sign a document containing an agreement, making a disposition of property, entering into a contract, granting a release or containing any declaration, shall be punished with imprisonment. The same punishment applies to any individual who shall make use of any such document.

Massage in Headache.

Dr. Norström, finding that a good many cases of headache occur where, though the symptoms are more or less like those of migraine, the remedies suited to that affection are of but little use, examined the heads of such patients carefully, and came to the conclusion that the pain must depend upon inflammatory thickenings existing at the insertion of various muscles, especially the sterno-mastoid, the temporal, the scaleni, the trapezius, and the occipito-frontalis. These indurations do not usually produce any local pain, and therefore are generally unnoticed both by physician and patient. They are commonly the result of "taking cold," and the headaches they cause can be traced to changes in the weather. Dr. Norström obtained excellent results by regular massage of these indurated spots, the sittings lasting for about a quarter of an hour. Similar treatment is also efficacious where the headache is due, as it sometimes is, to enlarged lymphatic glands. Of course, little result can be expected from massage in headaches of anæmic or of hysterical origin, or where there is organic cerebral disease.—*Lancet*, Sept. 27, 1890.

A New Form of Nasal Tampon.

The *Deutsche Medizinal-Zeitung*, Sept. 25, 1890, describes a new form of nasal tampon devised by Ignazio Dionisio, as published in the *Monatsschrift für Aerztliche Polytechnik.* By means of this instrument the nasal cavity can be tamponed, in case of hemorrhage, without interfering with nasal respiration. The principle is that of the Trendelenberg canula for the trachea. A tube similar to a catheter, surrounded by an elastic rubber bag, is introduced into the nasal cavity, and the bag is distended with air or water. The bag adapts itself to the cavity, while the respiratory current of air passes through the tube. By this method septic decomposition of blood absorbed by the tampon is impossible.

Apomorphia for Croup.

The emetic properties of apomorphia may prove of great service in a variety of conditions, one of which is croup. One-eighth of a grain may be dissolved in six teaspoonfuls of water, and of this a teaspoonful may be given to a child every five or ten minutes until emesis results. The second or third dose usually does the work. One great advantage of apomorphia is that it may be given hypodermically to persons—old or young—who cannot, or will not, swallow.

THE

MEDICAL AND SURGICAL

REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

KOCH'S METHOD FOR CONSUMPTION.

Since our Editorial of November 15 was published, the formal announcement by Professor Koch of his method of treating consumption has been cabled to this country and published in the newspapers. A careful examination of this announcement does not lead to any modification of the opinions already expressed in the REPORTER. It is probably safe to assume that Koch's method accomplishes something very remarkable in the treatment of lupus, as the cases alluded to in his paper are of a very striking sort, and—besides the credence which his accomplishments thus far have entitled him to—his operations have been witnessed by men of well known ability and integrity. When it comes to consumption, however, we think the announcement is of a most unsatisfactory character. When sifted, Koch's sole claim seems to be that by his method of treatment the condition of patients with incipient phthisis may be improved—how much, or how soon, his communication does not say; while for cases of advanced phthisis, with marked cavities, he makes no distinct promises. Rightly understood, this seems to be about what we had already accomplished in the management of this disease. Humanity prompts the hope that Koch's method may accomplish all that the most enthusiastic have claimed for it; but scientific men must carefully distinguish between what is legitimate as hope, and what is to be accepted as a demonstration.

The rush of patients and physicians from various parts of the world to Berlin, which followed Koch's announcement, must be deplored; because, taking this as Koch and his immediate followers present it, there is nothing to be got at Berlin except his curious remedy—his nostrum. The mode of administering it Koch seems to have disclosed, and in this there is nothing which the humblest practitioner in medicine cannot imitate, when once the proper remedy is put within his hands.

We must repeat our condemnation, already expressed, and still strongly felt, against the way in which Koch keeps to himself the nature of a remedy which is expected to be of so great service to mankind. The claim that this is done in the cause of science may be honestly put forth, but it can by no means be accepted. The right course, the course in accordance with the principles contained in the Hippocratic oath, and the principles which have been the glory of the medical profession, ever since it had the slightest claim to be a profession—would lead, we think, any purely humane, unselfish man at least to tell the world how he prepared a remedy, for which such great virtues are claimed, and of which mankind stands in such sore and pressing need. If his method were perfect, no time could be too soon for such a gift to his fellow-men; and if it were imperfect, we

think a sincere and a thoroughly good man would then tell what progress he had made, in the hope that perhaps some more fortunate, or possibly more ingenious investigator might reach the goal before he did, and so much the sooner give to the numberless sufferers with consumption the rescue, while waiting for which they might otherwise die.

NOT A FAST BUT A FRAUD.

In this issue of the REPORTER, we publish a letter signed by Dr. W. F. Hertzog and Dr. W. D. DeLong, containing a very interesting and conclusive report of their examination of Mrs. Wuchter, the alleged faster, near Allentown, Pa., to whose case reference has been made in the REPORTER a number of times. This report and the most recent developments of her case furnish very satisfactory evidence of the correctness of the opinion expressed in the REPORTER when the case was first commented on, September 27, 1890. About that time, the family physician of this woman and her husband and the *New York Herald* made an attempt to work upon the sympathy of the public by decrying the criticisms of the REPORTER, and especially the caption of our Editorial.

In closing the subject, however, we think it proper to say that the whole history of the case furnishes abundant confirmation of the opinion expressed by the REPORTER September 27, 1890, and justification for entitling the Editorial in regard to it, "Not a Fast but a Fraud."

A LEPER COLONY..

We note with interest that Dr. William H. Ford, President of the Board of Health of Philadelphia, has addressed to Dr. J. B. Hamilton, Surgeon-General of the United States Marine Hospital Service, a letter, in which he proposes, at the suggestion of Dr. Duhring, of this city, that the Government shall provide a leper colony to which persons having leprosy, who may be detected in the United States, may be sent, with a view to their isolation under less trying circumstances than accompany isolation as practiced now in the different localities in which they are found. He proposes that the Government shall provide places where persons suffering from leprosy can be separated from the public and humanely cared for and treated in such a manner as not to deprive them entirely of the comforts and enjoyments of life. The protection of the public and the humane management of the unfortunate subjects of this disease are the two-fold objects that would be accomplished by this course.

He adds that it is the consensus of opinion that persons suffering from leprosy, on account of its peculiar nature, its chronic character, and the abhorrence with which the public view it, should be removed from the midst of society and humanely cared for and treated in places specially set apart for this object. It is impracticable for towns or cities or even States to provide such places on account of the expense: the number of cases not being large enough to warrant the necessary expenditure. He asks what is finally to be done with the lepers now ill provided for, and those that shall be discovered in the future? They cannot be treated in general hospitals, except for a very limited time. It is difficult to return them to their native countries, though most of them are unnaturalized foreigners. Where there are hospitals for the treatment of contagious diseases (and few places have such special institutions) temporary provision might be made for them. Here they must necessarily be secluded in unfrequented apartments, denied intercourse with relatives and friends, shut out from the world, denied the freedom of outdoor exercise because of the popular aversion to the disease, and doomed to a life of suffering and, what is worse, mental anguish on account of their deserted and hopeless state. What is to become of lepers who may happen to be discovered in places which have not even such inadequate means

for their care? Dr. Ford says there are probably to-day lepers in every large city in the country which necessitates providing many places for their treatment. Barring the expense, it is not wise to multiply these settlements. Nevertheless the public must be protected, even though it be at the expense of the liberty and happiness of those unfortunate subjects whose condition could be greatly ameliorated by their segregation in one or more well appointed stations in convenient parts of the country.

Dr. Ford's suggestion deserves careful consideration, and we believe might well be adopted, although the readers of the REPORTER know it is our opinion that leprosy is not contagious in the ordinary sense of the term, and that lepers ought not to be treated as if it were; nevertheless, we believe that in the present state of science and the present condition of public opinion, it would be very advantageous if the Government would appoint and maintain a place where lepers could be sent and treated, for their own good and for the comfort of the community—if not for its protection. We commend this matter to the thoughtful consideration of the readers of the REPORTER. Surgeon-General Hamilton has already indicated his approval of the idea in general, while pointing out the fact that the United States Government cannot force citizens affected with leprosy to leave their homes. This we quite understand; but would be glad if the Government could provide a place for voluntary segregation of citizens and compulsory segregation of aliens, so that the practicability and desirability of the method might be tested.

TREATMENT OF ECZEMA IN CHILDREN.

The treatment of eczema is not so definitely settled as to be one for all cases. Every case has its own peculiarities and demands special attention. Remedies which may be valuable in one may be found worthless in another. The treatment of the disease, when occurring during childhood, must be different from that employed in adults. Realizing this, Dr. E. Saalfeld, in the *Deutsche Medicinische Wochenschrift*, July 3, 1890, has endeavored to place the treatment of eczema in children upon a rational basis.

The disease in children owes its origin, in many cases, to excoriation, or chafings, between the nates, in the bend of the knee, and in the folds of the neck. This is most frequently met with in fleshy children. In eczematous intertrigo, when the usual household remedies, such as salves and powders, have failed to give relief, a careful regulation of the diet and a change of food is primarily indicated. Very frequently diarrhœa will be an accompanying symptom, and this should be checked at once. If the skin is highly inflamed, a cool application of equal parts of a five per cent. solution of boric acid and lead water, and the use of a five per cent. boric acid ointment will be found most beneficial. If the skin is moist, it should be dried with powder, before the ointment is applied. In cases of eczema of the head and face the diet should be very plain and contain as little fat as possible. The bowels should be kept open by means of suitable laxatives. The flakes and scales should be moistened with olive-oil and removed. The underlying skin may then be treated with an ointment composed of boric acid, one and one-half parts; oxide of zinc and starch, of each five parts; vaseline, thirty parts.

In general eczema, especially of a scrofulous origin, the constitutional treatment plays a most important part, and should include a careful regulation of the diet, the administration of cod-liver oil in connection with phosphorus, and arsenic internally. The local treatment in these cases should consist merely in the application of vaseline and subsequent powdering.

Naturally, before any treatment for general eczema is instituted, a careful examina-

tion of the skin should be made, in order to exclude the possibility of the disease having been caused by the presence of parasites.

In conclusion, Saalfeld warns against the use of tar, since it is very irritating to the skin of children. Its place may, however, be ably filled by an ointment composed of white precipitate of mercury, one part; balsam of Peru, five parts; and benzoinated oxide of zinc ointment, thirty parts.

Naturally, the hygienic surroundings of the patients is very important; well-ventilated rooms, fresh air and scrupulous cleanliness, all contribute largely to a rapid recovery.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

TRANSACTIONS OF THE MICHIGAN STATE MEDICAL SOCIETY, for the year 1890. Vol. xiv. 8vo, pp. 479. Detroit: O. S. Gulley, Bornman & Co., 1890.

This volume includes the transactions of the Society at its twenty-fifth annual meeting, at Grand Rapids, June 19 and 20, 1890. It is impossible to review it satisfactorily, because it contains no less that thirty-five papers and addresses, besides the discussions and a number of reports, etc. The subjects cover a wide range, and are all of quite unusual excellence. It is evident that the medical profession of Michigan is thoroughly modern in its medical ideas, and that it comes to the annual meetings prepared for a vast amount of admirable work.

The volume is well printed, and firmly but simply bound. It is in every way a credit to the Society, and to the Editor, Dr. Charles W. Hitchcock, of Detroit.

INDEX CATALOGUE OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, UNITED STATES ARMY, Vol. xi, quarto, pp. 1,102. Washington: Government Printing Office, 1890.

As each new volume of the Index Catalogue appears, we have anew the pleasure of praising the industry and skill of its Editor, and the wise liberality of the Government, which puts so valuable a work within the reach of all investigators in medicine. The eleventh volume, which has just come to hand, contains the words Phædronus—Régent. We notice the subject of phthisis covers seventy-nine pages, which shows the enormous literature it has devoted to it.

TRANSACTIONS OF THE AMERICAN DERMATOLOGICAL ASSOCIATION, Thirteenth Annual Meeting, Boston, Mass., September 17, 18, and 19, 1889. 8vo, pp. 80. New York, 1889.

This volume, according to the table of contents, contains a number of papers read before the Society at its meeting in 1889. But in looking through it we are surprised to find that, with perhaps one or two exceptions, only the titles of the papers are given. The discussions on them, however, are in most cases so full that one gets a very good idea of what the author must have said. It is a pity, nevertheless, that both papers and discussions could not have appeared together. We hope this may be the case with succeeding volumes. The original articles are too valuable to be lost.

ESSENTIALS OF ANATOMY AND MANUAL OF PRACTICAL DISSECTION, TOGETHER WITH THE ANATOMY OF THE VISCERA. Prepared especially for Students of Medicine. By Charles B. Nancrede, M. D., Professor of Surgery in the University of Michigan, Ann Arbor, etc. Third Edition, revised and enlarged. 8vo, pp. x, 388. Philadelphia: W. B. Saunders, 1890. Price, $2.00.

The present edition differs from its predecessors in containing a series of thirty colored plates, taken from the works of Maclise, Savage, Quain, and Hirschfeld. They have been chosen with good judgment, for the purpose of making the book useful to the student in the dissecting-room. The rest of the book abounds in good wood-cuts, there being one hundred and eighty in all, which amply illustrate the text. There is also a good index. In fact, it is much more of a book than most of the others intended for the same class of readers, and is most excellent in plan, style and contents.

Correspondence.

The Alleged Faster.

To the Editor.

Sir: On October 20, we visited Mrs. Adam Wuchter, of White Hall, Lehigh Co., Pa., whose case has been so fully discussed in the Reporter, and who was said by her friends to be suffering from a malignant affection of the œsophagus which made her unable to swallow, and to have lived in this condition, without food or drink, for about seven months. We could not get a history of her ancestry; but she was an only child. These are often "spoiled," and likely to become nervous. Prior to her present illness, she had spells of sickness that lasted for months; and then she would get well enough to do her house-work again. In the present illness she lost her voice suddenly, and has been in bed for nineteen months.

On looking at her, we saw a woman somewhat emaciated, her eyes covered with a cloth, on removing which we found the eyeballs turned up. Taking hold of her right arm we found it apparently paralyzed. In trying to percuss her chest and abdomen, there seemed to be diminished sensibility of the skin of those parts; but her limbs could be freely handled without giving her

pain. The radial pulse could not be detected on account of the muscular tremors which she constantly had when any one attempted to feel it; but there was a good heart action. She had no œdema and no bed-sores, such as might be expected from long lying in bed and starvation. She talked aloud and glibly enough to show that her mouth was not dry. She told us to give her water to drink, so that we might satisfy ourselves that she could not swallow. But when we brought the cup near her lips she had a regular attack of hysterical convulsions. Before we went off she treated us to a spell of hysterical dyspnœa. Her husband said she had urinated only once since Good Friday! (It will be remembered that Ultzmann, who had such a large experience in the treatment of disorders of the genito-urinary organs, saw cases of anuria in hysterical women which lasted from one to two days. Benedikt reports a similar case of eight days' duration, but nobody ever claimed such an absurd period as does this woman's husband.)

Our diagnosis of the case was hysteria; for the manifestations of hysteria were so prominent as not to be mistaken. If there were an organic trouble in her case, the hysterical manifestations would have been less prominent by this time. Before we had a right to reject the diagnosis of cancer of the œsophagus which had been made public, we had to exclude that. In regard to this point the woman did not, in our opinion, have the cancerous cachexia; no tumor of any kind was visible on the outside of her neck, and no instrument was ever passed down her œsophagus to see whether any *real* obstruction of any nature existed. If she had acquired aphonia from an organic disease, it would not have appeared suddenly. Last, but not least, she would have died before this. Mackenzie says the average duration of life in his one hundred cases was eight months; the maximum being sixteen months, the minimum five weeks.

As to her alleged long fast, we will simply say that her condition when we examined her did not warrant belief in it.

As to prognosis, we, at that time, predicted her final recovery, and recent developments are justifying this prognosis.

Yours truly,

Oley, Pa. W. F. Hertzog, M. D.,
Pikesville, Pa. W. D. DeLong, M. D.

November 12, 1890.

Correction.

To the Editor.

Sir: Your report of my short paper before the New York State Medical Association (Reporter, November 8, page 537) is very correct; but by mistake it is credited to Dr. McCollom. If it is worth anything, I want the credit; if it is not, then Dr. McCollom does not want the discredit.

Yours truly,

Ira B. Read, M. D.

66 East 126 St., New York.

[We regret the error of one of our New York correspondents, which was due to his want of familiarity with the faces of the speakers at the last meeting of the New York State Medical Association.—Ed. Reporter.]

Notes and Comments.

Relation of the Sexual Functions to Mental Disorders of Women.

At a recent meeting of the British Gynæcological Society, Dr. Robert Barnes read a paper in which he said the association of nervous disorders with disease or disordered function of the sexual organs in women was of frequent occurrence. He discussed the influence upon the organism as a whole of the menstrual and climacteric periods, both of which put the nervous system to a severe strain. Consequently any inherited or acquired weakness of that system was peculiarly liable to make itself felt at one or other of those momentous epochs. Many nervous disorders were associated with dysmenorrhœa and disappeared upon the removal of the cause. In other instances the disordered mental condition was associated with "copremia," by which he designated a combination of spanemia and toxemia. He related several examples of the supervention of insanity consequent upon displacements of the uterus, and their relief after suitable local treatment. He then discussed the influence of the removal of the uterus and ovaries in the production of insanity, and considered the propriety of operating when the association of the mental condition and certain disorders of the reproductive organs was such as to justify the assumption that they stood to each other in the relation of cause and effect. More careful examination should be made of the pelvic organs of insane women with the view of endeavoring to remedy any local disease when this was

possible. He particularly insisted upon the necessity for this course in the case of women suffering from puerperal mania.

In discussing the paper Dr. Savage said that it could only be in a very small proportion of cases of insanity in females that any good could be done by treatment directed to the reproductive organs. He raised the question as to whether the confirmed habit of masturbation was the cause or the effect of the mental condition. He insisted upon the diagnostic value of hallucinations of the sense of smell as indicating the coincidence of some affection of the uterus or its annexes. He protested against procuring abortion with the view of cutting short an attack of insanity in pregnant women, or in those who had previously suffered from puerperal mania. He remarked that in physical characteristics the degenerate man tended to approach woman and *vice versâ*, and he asked whether women who presented such masculine features as an abundant growth of hair on the face, etc., were more prone to this kind of break-down, and whether degenerative changes in the reproductive organs were usually associated with any abnormality in this respect.

Dr. Wilks insisted upon the difficulty of distinguishing between what was a constitutional and what a local disorder. He was quite prepared to admit that local causes might determine nervous disorders, and this was peculiarly the case in regard to diseases of the reproductive organs. He intimated his opinion that in all probability confirmed masturbation was the result, or the immediate forerunner, of insanity.

Dr. Hack Tuke, while admitting the influence of disordered menstruation upon the mental functions, said that his experience had taught him that disappointment but too often followed gynæcological treatment in these cases. He instanced the meagre results obtained at certain American asylums where special measures had been taken for the study of the correlationship of the two classes of disorders. At the same time, he said he had met with a number of cases of mania and epilepsy in which he would have liked to have seen oöphorectomy performed. He did not see what objection there could be to performing the operation in such cases. He concurred in the view that it was undesirable to procure abortion in cases of insanity in women.

Dr. Mercier pointed out that any addition to the functions of the body such as occurred at puberty, and any abstraction of functions as by castration, was liable to give rise to more or less serious and permanent disturbance in the distribution of nerve force, the proper play of which was essential to perfect equilibrium.

Concussion of the Spine.

About many subjects in medicine and surgery there lingers much indefinite knowledge. It is partly tradition handed down from one generation and one author to another, and yet it is not thrown aside because of a lack of anything more definite to take its place. It is therefore an agreeable task to chronicle an advance in positive knowledge. In no class of injuries has this been more needed than in those of so-called "concussion." Hitherto the views of Erichsen and Page have been authority, and they undoubtedly contain much that is fundamental and generally admitted to be true. It has been the fortune of an American surgeon, Dr. B. A. Watson, of Jersey City, to supplement these ideas by the published results of an elaborate series of experiments.

In the course of the work one hundred and forty-one dogs were experimented upon. The animals were uniformly dropped twenty-five feet, and were so hoppled in one hundred and thirty-five cases that the blow was delivered on the nates, while the spine formed a nearly perpendicular line to this point. In six other cases the blow was received along the spine, while the head of the animal was sufficiently raised to prevent its coming in contact with the floor. Immediately before each trial a full record was made of the animal's weight, age, sex, pulse, temperature, respiration and of the condition of the pupils. These observations were carefully resumed the day after the trial. Full pathological examinations, in gross and microscopically, were made by Dr. Frank Ferguson.

We can but briefly allude to the well-analyzed results given by Dr. Watson. The injuries received by the animals "were frequently compound and nearly always complicated, while in degree of severity they differed widely, being in some instances quickly fatal and in other cases they were so slight as to be imperceptible either in the *post-mortem* or microscopical examinations." The last record of vital conditions in the animals surviving the fall was made just be-

fore they were killed by chloroform. In 5 cases there were fractures of either the ribs or vertebræ; in 11 an incomplete rupture of the sacro-lumbar ligaments was found, but in every instance some pathological change had resulted also in the cerebro-spinal axis. Quickly fatal results happened in 4 cases. The spinal ligaments were stretched in 5.

Of injuries to the viscera the most frequent was hemorrhagic infarctions of the lungs, 36; then followed, in order, congestion of kidneys, 32; lacerations of liver, 15; ecchymosis of psoas muscles, 7; pneumonic hepatization, 5; hemorrhagic infarctions of liver, 4; and others of less frequent occurrence, including rupture of spleen, 1; of liver, 1; of kidneys, 2; of pelvic blood-vessels with considerable hemorrhage, 2; and of bladder, 1.

Dr. Watson intelligently discusses many of the problems which this series of experiments presents. We deem his conclusions of sufficient importance to present them in outline as follows:

1. Concussive accidents never produce pathological changes in the cord unless great force has been applied to the spine. These cases are generally complicated with vertebral fracture or dislocation, rupture or stretching of vertebral ligaments, or distant injuries so severe as to quickly prove fatal.

2. The symptoms develop immediately and are rarely intensified by morbid changes in the cord; exceptions, fractures, dislocations and slowly developing hemorrhage causing pressure on the cord.

3. It is very difficult to demonstrate stretching of vertebral ligaments on living subjects. The lesion is frequently overlooked on autopsy.

4. Injuries of the cord, with visceral injuries in addition, develop symptoms dependent on the existing complication. The termination of the case rests on the character of the traumatism.

5. Concussive force, though remotely applied, frequently results in the production of severe and even fatal traumatisms in various organs within the three trunk cavities.—*Medical Record*, October 18, 1890.

Strychnine as a Preventive of Tetanus.

The *Bulletin Médical*, September 21, 1890, says that Peyraud, continuing the application of his theory *similia similibus*, not for the cure but for the prevention of infectious diseases, has just communicated to the Bordeaux Medical and Surgical Society some experiments relative to the power of strychnine to prevent tetanus. According to Peyraud, as strychnine acts upon the nervous system in such a manner as to provoke a state altogether similar to that produced by the virus of tetanus, it should put the nerve cells in such a condition that they can no longer react to infection by tetanus. This is his theory.

On April 23, 1889, he made sub-cutaneous injections of a solution of strychnine, containing one-sixtieth of a grain to the fluid drachm, in the case of thirteen rabbits of various weights and ages, but none older than five or six months, the youngest being four months old. A half (Pravaz) syringeful was injected under the skin of the flank. The following day an exactly similar dose was injected. On the 25th, he increased the dose a little (by one division of the syringe-piston). Ten of the animals were seized with convulsions, and three died; three were unaffected. The next day the first dose was resumed. Only two of the animals had convulsions, and on the 27th, three. Tolerance to strychnine injected under the skin does not, therefore, seem to have been established. On the evening of the 27th, he made his inoculations with a little rabbit made tetanic with the powder of hay. This animal had pleurosthotonos so pronounced that it was literally bent double on the inoculated side. He first made six inoculations under the skin of the head, always using a small particle of tissue taken from around the tetanus-bearing wound. He says: "I even scraped with my scalpel the serum and the pus from the wound, and dried this scalpel upon the lips of the inoculation wound, that the inoculation might be quite certain and complete." The small wound was sewed up hermetically. At this time the animal with tetanus died. It was replaced by another in the same condition, but a little less moribund than the preceding, and Peyraud then finished the inoculation of the four remaining dogs poisoned with strychnine, and of two unprotected animals, as a control experiment. Again, a small piece from the wound and the fluids from the rabbit which died of tetanus were used to inoculate two other unprotected animals. Thus fourteen rabbits were inoculated; ten prepared by strychnine, four unprepared, as control experiments. On April 28, Pey-

raud took four of the rabbits injected with strychnine and completed their preparation by a fresh dose of strychnine—a little less than that given on the 27th. One only had some very slight convulsive movements. On May 1, one of these animals was seized with tetanus and died in opisthotonos the following night. Two more died in the next two days, but the fourth, though it showed embrosthotonos and refrained from food for two days, did not die. The protected animals, which did not receive any supplemental injection of strychnine after inoculation remained well except one, which had a slight contracture of the right hind leg. All the animals used for control experiments died of tetanus between the second and fourth days. Peyraud says he has obtained the same results in another series of cases, and he believes his results demonstrate that strychnine has power to prevent tetanus.

Experimental Investigations with Tuberculous Milk.

The *Deutsche Medizinal-Zeitung*, Sept. 25, 1890, contains an abstract from a highly interesting paper by Dr. Bang, of Copenhagen, published in the *Deutsche Zeitschrift für Thiermedicin*, Bd. 17, Heft 1. From fifteen to thirty minims of milk from twenty-eight tuberculous cows with healthy udders were injected into the abdominal cavities of as many rabbits. The milk of only two cows proved infectious. The milk of eight highly tuberculous women produced no evidences of tuberculosis. Abcesses which occurred at the site of innoculation or in the abdominal cavity were not tubercular. Sweet and sour cream, obtained from tuberculous milk containing many bacilli proved virulent. Butter made from the milk (containing many bacilli) of a cow with advanced tuberculosis of the udder, injected into the peritoneum, produced severe tuberculosis. Feeding rabbits with such butter was followed by a like result. The use of butter obtained from tuberculous animals need not therefore be regarded as especially dangerous. The secretion of milk in cows with advanced tuberculosis—at best but slight, is permitted to cease entirely. Besides, such cows rarely supply tuberculous milk, from which by centrifugal action the bacilli are largely removed.

Gebhardt has demonstrated that the danger of infection is in direct proportion to the number of bacilli. These experiments emphasize the necessity of paying careful attention to tuberculosis of the udder. Further investigation demonstrated that the bacilli or their spores are not deprived of their virulence by exposure to a temperature of 176° F. but that for this a temperature of 185° F. seems to suffice. A temperature of 212° F. is absolutely destructive of the bacilli. This statement as to the degree of heat applies to the tuberculous fluid, not to the bath. Two rabbits, fed with tuberculous milk heated to 140°–149° F. showed signs of mild tuberculosis, while of six given the milk unboiled, all succumbed to typical tuberculosis. Rabbits which received milk heated to 158°–167° F. remained absolutely free from infection. A rabbit, fed for seventeen days with unboiled tuberculous milk, which died accidentally, showed only tubercules in the lymphatic glands above the fauces—clinically the primary site of tuberculosis in cattle and swine. Dr. Bang considers it probable that a large proportion of tubercular (scrofulous) affections of the cervical glands in children owe their infection to tuberculous milk.

Tolstoi and Physicians.

Dr. A. B. Holder has in the *Memphis Medical Monthly*, October, 1890, a very interesting short paper on the opinions of Tolstoi about physicians, as contained in his *Kreutzer Sonata*. In concluding the paper, Dr. Holder says :

"Tolstoi is a fanatic ; we may go a step further and doubt his sanity. No sane mind would see human nature in such sombre colors ; he is morbid ; the good men do finds no responsive chord in his mind, or rather as rays of light entering a different medium, are deflected from the straight, so good is deflected and distorted till in his perception it seems evil. This is a form of insanity.

"This miserable pessimist, great man and great mind though he be, finds no good in aught human ; its institutions, its governments, its churches, its priests, its professions, its passions and opinions, all are bad ; marriage is not only a failure but a sin—a 'legalization of sensuality.' His theories are not new ; many years ago I listened with open-eyed wonder while a Shaker Elder from a community in our own

State declared that all love was passion and celibacy the only sinless state. He was gentler and less fanatic and intolerant than the author of the *Kreutzer Sonata*, and I felt there was some truth in his reasoning.

"I have ever doubted if a bit of paper with a seal, and a few words mumbled by an ignorant magistrate, made sexual intercourse between an unloving and ill-mated man and woman less adultery than was the embrace of two young lovers whose prudence in an unguarded moment yields to passion; whether the woman who weds a man for his wealth or position is less an unchaste woman than she who receives her lover without consent of Church or State *for love of him*. I know the world regards them differently; 'honored well are charms to sell, if priests the selling do,' but—I doubt. Still, as it now stands, marriage is the best solution ever yet offered to the great problem, and the man who would endeavor to solve the problem without marriage forgets that it is a human and not an ideal and angelic race he deals with."

Infant Mortality in Chili.

Theodore Child says, in *Harper's Magazine*, November, 1890: The poor alone live in public, either in the unhygienic sheds and cottages of the city, or in the rudimentary cane huts of the suburbs, where the *peones* and their families squat on the ground like wild Indians, and manifest fewer evidences of civilization than the miserablest of the Russian peasantry. For the *peones*, life is truly a question of the survival of the fittest, inasmuch as none but the very strongest can live through the trials of childhood.

Thanks to the fearful dens in which the poorer classes of Chili live, the infant mortality is enormous. On the other hand the *peones* and their women folk are prodigies of hardy endurance; they are indeed the fittest and strongest of their generation, all the weaker having died in the first few months or years of their struggle against insalubrious circumstances and conditions. These infant victims of defective sanitary arrangements do not occasion grief or mourning by their premature departure from this world; their mothers believe that the little souls immediately go to paradise and become angels, and so they are called *angelitos*, and their death is a pretext for rejoicing, and inviting neighbors to drink and dance. The little corpses are kept for days and days; often you will see women in the trains and the horse-cars with dead babies in their laps; the photographers, too, are constantly having infant corpses brought to them to make souvenir portraits. In the country the death of an infant will interrupt work for a week or more. In one village that I happened to visit an epidemic of measles had made half a dozen *angelitos*, and for nearly three weeks no work had been done for many miles around. The whole population had been keeping up a continuous wake, dancing, singing and drinking round the *angelitos*, who were dressed up like church images, and surrounded by burning tapers. This belief in *angelitos* and the custom of wakes also prevails in Peru, Bolivia, and the Argentine.

Treatment of Pelvic Inflammation.

In a paper entitled: "How shall we Treat our Cases of Pelvic Inflammation?" read before the Southern Surgical and Gynecological Association, at its last annual meeting, Dr. R. B. Maury gave a comprehensive résume of the pathology of chronic pelvic inflammation as it has been clearly demonstrated by Bernutz, by Polk, Coe and others, and by the results of abdominal section. This pathology is that of pelvic peritonitis dependent upon tubal disease—not cellulitis. Dr. Maury declared that the term chronic cellulitis is a misnomer—a pathological condition which exists only in the imagination of the physician; a term which has been productive of pernicious results in practice, and which should no longer be used in connection with non-puerpural chronic pelvic inflammation.

When this pathology rests upon such positive and abundant evidence, the question might be asked: Why re-open a discussion upon it now? Because it is evident from our Society proceedings and hospital reports that great confusion exists in the medical mind in regard to it. Dr. Byrne's case, discussed in the New York Obstetrical Society during the present year, was taken as an illustration. In speaking of such cases the great tendency to relapses in chronic pelvic inflammation was illustrated by two cases in which pus tubes were found five and seven years after attacks of peritonitis and when it was supposed the patients were entirely restored to health.

Upon the subject of treatment, Dr. Maury

admitted that by non-surgical therapeutic measures large intra-peritoneal exudations are often absorbed, and that even some tubal and ovarian inflammations entirely disappear and recovery seems complete. But this is the exception and by no means the rule.

For the radical cure of chronic pelvic inflammation non-surgical treatment fails in a majority of the cases. A great many women, suffering to a moderate degree, continue to do so in spite of the best-directed non-surgical measures, and perhaps wisely elect not to undergo operation.

As a rule the only radical and permanent relief is afforded by removal of the diseased appendages. The treatment of pus collections of course requires abdominal section.

Fatty Heart in a Young Subject.

Dr. R. Lowther, M. D., reports in the *British Medical Journal*, October 18, 1890, the following interesting case of fatty degeneration of the heart which is by no means common early in life, though cases have been reported as early as the second year.

A young man, 22 years old, apparently robust, went out for a brisk walk with two friends. After walking two miles they began to hurry, and he suddenly fell down, dying instantly. For three years he had been a footman, and was accustomed to partake largely of animal food three times a day, and of beer in considerable quantities. At the *post-mortem* examination the chest muscles were found thickly covered by adipose tissue. The pericardium had lost entirely its ordinary appearance; it showed no trace of fibrous tissue, but resembled a thin plate of purely fatty character, so friable that it tore when slightly raised. The heart was of normal size, measuring 5 inches by 3½ inches at the base, and had also undergone marked fatty degeneration. Both coronary arteries were embedded in adipose tissue, which shaded off on each side, and only disappeared in the central third of the intracoronary portion of the ventricles. The infiltration in the course of the coronaries penetrated the substance of the muscular tissue to fully two-thirds of its thickness, and these vessels were shrivelled. The heart as a whole was soft and flabby, probably from the presence of interstitial fat. Both auricles and ventricles were fully distended. The endocardium was slightly fatty, and all the valves showed yellow streaks of fatty degeneration. The jugulars also were distended, and the lungs congested. These conditions clearly showed that the heart had ceased to act in systole, death being due to syncope.

Simulo.

Simulo is the *capparis coriacca*, a Peruvian shrub, similar to that of Europe, which furnishes what is known as "capers." The seeds of simulo have been used in the treatment of epilepsy and hysteria.

The *Therapeutic Gazette*, October, 1890, says—quoting the *American Journal of Insanity*, July, 1890—that Dr. V. Paulet reports a number of cases of hysteria treated with simulo, in which it appears to have decidedly good effects. He also employed the drug in a case of ovaritis with severe pain, and one of double pregnancy accompanied by nervous palpitation, violent headache, and complete insomnia, and obtained absolute relief in both cases. As regards its use in epilepsy, he does not think that it can supplant the bromides, but that in some cases and under certain conditions, not very well defined as yet, when the bromides seem inefficacious or contra-indicated, it may be very useful. In one of his cases also chorea was apparently benefited by simulo.

The alcoholic tincture of the drug is a bad form for administration in epilepsy and hystero-epilepsy, since, if given in any quantity, the alcohol may neutralize the good effects. As regards the safety of the medicine, he considers it quite innocuous in large doses. It appears to have, he says, no effect on the pulse or respiration; it causes no depression, no mental excitement, and no disorder of digestion.

Tubercular Pharyngitis.

The *Deutsche Medizinal-Zeitung*, September 25, 1890, contains the following conclusions of Dr. Aigre, as published in *El Siglo Médico*, No. 90, 1889:

Miliary tuberculosis of the pharynx is a rare disease. There is no doubt as to the exciting causes. The affection may exist without a lesion of the larynx. The condition is anatomico-physiologically a subacute or acute tubercular pharyngitis. The lesion appears to concentrate itself upon the mucous membrane and about the glands,

and no disposition is observed to extend deeply to the vessels or between the muscular fibres. Tubercle bacilli are present, with a large number of various other micro-organisms, which take an active part in the ulcerative process. The pains in the ears which so frequently occur probably depend upon an extension of the disease to the Eustachian tube. Infarction of the cervical glands is not a constant symptom. Constitutional treatment is of no avail. Means should be used to relieve the difficulty of deglutition to permit of liberal and full alimentation, as the best treatment of tuberculosis. Local treatment fails. As palliative measures, nutritive enemata and local applications, four or five times daily, of a combination of one part of morphine with twenty-five of glycerine, or of a solution of one part of cocaine to fifty of water, or of a combination of both, are indicated.

Etiology of Croupous Pneumonia.

Mestovitch (*Bolnitchnaya Gazeta Botkina*, June 12, 1890), says that he is convinced by his experimental work that croupous pneumonia is due to a special micrococcus, and gives the following conclusions. The number of phagocytes is considerably increased in animals that are going to recover from infection with the diplococcus and the phagocytes are not present in animals fatally infected.

This fact was demonstrated by introducing the virus sub-cutaneously in a delicately prepared glass prism; after the lapse of a few hours the specimens were examined and the presence or absence of increase in the phagocytes was looked for under the microscope. Cases in which the phagocytes were increased made a good recovery; in those where the increase was absent the results were fatal.

The author has shown experimentally that the phagocytes are of mesodermic origin, and he suggests to the profession to find therapeutic remedies to increase the number of phagocytes, as the latter are the elements that eat away the pathogenic micro-organisms.

Camphor in Florida.

According to the *Druggists' Circular*, October, 1890, the Palatka *Herald* says that A. A. Beach has shown us specimens of distilled camphor from Florida-grown trees, and in his opinion the product is more profitable than any other business in the State. It can be distilled in any season of the year, and heat or cold do not effect it. The camphor tree is of very rapid growth. At four years old this tree attained a diameter of four inches and a height of eight feet, with large top and very thick foliage. The specimens shown us were much stronger than the imported article. Little time is required in distilling, the process being very simple.

Alvarenga Prize of the College of Physicians of Philadelphia.

The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about one hundred and eighty dollars, will be made on July 14, 1891. Essays intended for competition may be upon any subject in Medicine, and must be received by the Secretary of the College on or before May 1, 1891.

NEWS.

—Dr. Alfred Vogel, of Munich, well known for his work on Children's Diseases, died October 9, 1890, in his sixty-first year.

—Dr. Richard C. Norris was elected Registrar of the Obstetrical Department of the Philadelphia Hospital, November 10, 1890.

—The Trustees of a church in Philadelphia recently ordered the discontinuance of ringing the bell out of consideration for sick and nervous people in the neighborhood.

—By the will of the late Thomas C. Sloane, of New York, the Presbyterian Hospital in New York receives $10,000 and the Hospital for Ruptured and Crippled $5,000.

—It is said that Prof. Schrötter, of Vienna, is announced as a rival of Koch in the discovery of a cure-all for pulmonary consumption. Prof. Schrötter's remedy is said to be prussic acid.

—Dr. Delevan Bloodgood, the veteran Medical Director of the United States Naval Laboratory in the Navy Yard, Brooklyn, was sandbagged and robbed at 2 A. M., November 9, 1890.

—Miss Mary Garrett gave a reception in Baltimore, November 14, to ladies and gentlemen of the country who take an interest

in the Women's Medical School of the Johns Hopkins University.

—Dr. Boswell Gorham, a prominent physician, fifty years old, was shot dead by a negro named Duncan, on his farm near Lexington, Ky., November 11. No cause is assigned for the murder.

—The Russian Government has announced that at the end of five years, the decimal system of weights and measures shall be the only legal standard. Great Britain and the United States will then be the only civilized nations which use the ancient systems.

—The New York State Medical Association on October 24 elected the following officers for the ensuing year: President, Dr. Stephen Smith, of New York; Vice-Presidents, Dr. Douglas Ayres, Dr. A. T. Van Vranken, Dr. J. D. Tripp and Dr. Robert J. Meuzin; Members of the Council, Dr. W. D. Gavelock, Dr. J. B. Harris, Dr. George Douglass, Dr. Thomas B. Strong and Dr. A. L. Carroll.

—The N. Y. *World* (Evening Edition) of Nov. 7, says that a "long story" has been published at Newport, Vt., exposing the so-called "Union Medical Institute" of that place, which, it is said, had sold diplomas for $50 each in the West, and upon whose catalogue are given the names of incompetent men as professors with fictitious degrees. It is said that so great is the evidence of fraud against the promoters of the scheme that the matter has been taken up by prominent gentlemen in the State and placed in the hands of lawyers.

—The Southern Surgical and Gynecological Association, in session at Atlanta, November 13 elected the following officers for 1891: President, Dr. L. S. McMurtry, of Louisville, Ky.; Vice-Presidents, W. Gastohe, Atlanta; Dr. J. T. Wilson, of Sherman, Texas. The terms of Dr. W. E. Davis, of Birmingham, Ala., as Secretary, and J. H. Cochrane, of Birmingham, as Treasurer, were continued. The only change in the Judicial Council was the substitution of Dr. George J. Engelman, of St. Louis, for Dr. Bedford Brown, of Alexandria, Va., whose term expired.

OBITUARY.

DR. RICHARD J. LEVIS.

Dr. Richard J. Levis, one of Philadelphia's noted surgeons, died November 12, 1890, at his residence, "Cedarcroft," Kennett, Pa., after a very brief illness. After an attack of influenza from which he appeared to have recovered, he came to town on Saturday, November 8, and on Sunday he again became ill. On Monday pneumonia developed, and at 4.30 A. M., November 12, he expired.

Dr. Levis was 63 years of age, having been born in Philadelphia in 1827. He was a descendant of an old French family, one of which settled here at the time of Penn's occupancy. The father of Dr. Levis was also a physician, and his grandfather, Richard Levis, served as an officer in the Revolutionary army. Coming from a family which, for two centuries, had a representative in the medical profession, Richard J. Levis, upon his graduation from the High School, after having passed through the lower grades of the public schools, was entered as a student at the Jefferson Medical College. He was given private instruction by Professor Mütter, and devoted his studies more particularly to Surgery. In 1848 he graduated and at once commenced the practice of medicine and surgery, rapidly building up a lucrative practice. In 1859 he was appointed Surgeon to the Philadelphia Hospital. Shortly afterwards he was appointed surgeon to the Wills Eye Hospital, a position he filled actively for fourteen years, and at the time of his death was Emeritus Surgeon. In 1871 he was elected surgeon to the Pennsylvania Hospital, a position he held until 1885. In 1877, he was elected surgeon and lecturer on clinical surgery at the Jefferson College Hospital, serving this institution for ten years. He was one of the organizers of the Philadelphia Polyclinic and College for Graduates in Medicine, was President of the Board of Trustees, as well as Professor of Surgery. For twenty years he was surgeon of the Jewish Hospital. Among other positions filled by him were the Presidency of the Medical Society of Pennsylvania in 1885, and the Presidency of the Philadelphia County Medical Society in 1885-86.

On January 1, 1859, Dr. Levis became one of the Editors and co-proprietors of the MEDICAL AND SURGICAL REPORTER. His withdrawal from this connection was announced in the issue of March 21–28, 1863. He was always interested in the success of this Journal, and was a warm and respected personal friend of its present Editor.

FOR THE CURE OF

NERVOUS HEADACHES

SEDATIVE EFFERVESCENT

BROMO (WARNER & CO.) SODA

℞ Caffein 1 grain, Brom. Soda 30 grains in each heaping teaspoonful.

Useful in Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Seasickness and Epilepsy.

Dose and Composition.—A heaping teaspoonful, containing Bromo-Soda 30 grs., and Caffein 1 gr., in half a glass of water, to be repeated once after an interval of thirty minutes if necessary.

EFFERVESCENT ANODYNE

BROMO (WARNER & CO.) POTASH

℞ Caffein 1 grain, Bromide Potash 20 grains in each heaping teaspoonful.

Useful in Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Seasickness and Epilepsy.

☞ **Physicians** desiring the Potash Salt can obtain the same by ordering or prescribing **Bromo-Potash (Warner & Co.)**, the composition of which is: Brom. Potash 20 grs., Caffein 1 gr.

☞ The composition of the above effervescent salts is such as physicians can use with confidence, and you will please specify **Bromo-Soda** or **Bromo-Potash, Warner & Co.,** when ordering or prescribing to avoid the substitution of other "Bromos." Prepared only by

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

Clinical Lecture.

THE TREATMENT OF PULMONARY CONSUMPTION.

BY WILLIAM PEPPER, M. D.,

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE, UNIVERSITY OF PENNSYLVANIA.

Gentlemen: We discussed, at our last meeting, the question of change of climate for patients suffering with pulmonary consumption. You remember that we decided that we must be governed in the matter by the place from which the patient comes; the state of his finances, his sex and age, the stage of the disease and the places to which he or she is to be sent. This latter consideration, we remember, varies with the condition of the patient. We studied the character of life to be followed at these places of resort and the care which was to be insisted upon. I believe that the only time in the course of the disease when a change of climate is inadmissible is in the last stages of the disease. Even then we see most remarkable results in cases in which we are led, from a careful study of the condition, to expect but little. There is one consideration which we must not overlook in advising a change in a patient late in the disease. Ill-natured persons may say that we have kept the patient home until we have squeezed all the money we can from him, and then when the failure to produce a cure is palpable we send him away, to die far from home and friends. Hence in discussing this matter with a patient well along in consumption, explain the position; it is not your duty to deny the chance of improvement which exists; if the patient elects to take the chance, unless far advanced, allow him to go. Once started he should follow out every detail of hygienic care as fully as if at home.

If the patient decides to fight the disease out at home, do not neglect the slightest feature of the case; inquire into and regulate every circumstance and condition of the patient's life. No point is so small that you can afford to neglect it. First, in ordering more rest for the patient, determine if he is actually obliged to work for his living; many cases that cannot afford to go away, can lay off from work. If he need not work, have him take his breakfast in bed; not allowing him to expose himself to the cold air of a house in the early morning, when his own powers of resistance are lessened. Then he need not go down stairs until the house has been nicely warmed. He should dress leisurely, and should take as much out-door exercise as his strength permits and the weather allows; but do not allow him to become fatigued or depressed. He should lie down and rest both before and after his dinner, going out again after that meal. Do not simply tell your patient to live out-of-doors; then he is apt to overexert himself by staying out too much. He should rest and sleep, if possible, in the middle of the day. Promote the circulation and increase the tone of the muscular system by aiding and correcting digestion. Order food that will increase the resisting power of the body; so that he will cease to be so much affected by changes in the weather. He should retire early and sleep in a room which has not been used for a sitting room; the air must be pure. If it is pure in the bedroom the window had better be kept nearly, if not wholly, closed. The cold night air of a sleeping room may cause considerable irritation. Allow the patient to undress quickly, using candle light. Dress him carefully, in good pure woolens. The skin should be kept in good condition by baths and friction. A rapid sponge bath in salt water, followed by brisk rubbing, may be used; if this is too severe, rubbing oil over the body and removing it once a week, may prove beneficial. Make these

details the principal "business" of the patient's life.

Pulmonary gymnastics, in bringing in play the remaining healthy tissue and strengthening pulmonary muscles, is an excellent exercise. These must be advised whether the patient is at home or abroad. At all stages the digestion must be most carefully watched; hence make the rule never to give any drug which lessens the appetite or weakens the digestive powers. Such a drug does more harm than it can possibly do corresponding good.

There are so many signs and symptoms in pulmonary consumption that to attempt to prescribe for each one would soon develop polypharmacy. Try to grasp the most prominent and most urgent symptoms and attack them. There are from twelve to fifteen symptoms in this disease: cough, coated tongue, the pulse, the temperature, night-sweats, sleep, the condition of bowels, loss of flesh, pain in the chest, etc. Remember that no one remedy is in the slightest degree a specific. Since the discovery of the bacillus tuberculosis and its close relation to this disease, there has been no discovery of a mode of treatment which is more efficient in its results than was possessed before. We cannot destroy or even weaken the vitality or virulence of the bacillus, except by increasing the resisting power of the patient, producing more healthy cellular action, restricting the seat of the disease and restoring tone.

In considering the use of antiseptics or parasiticides, we know that if we could catch the bacillus and dose him well with bichloride or arsenic, we might do him extensive harm; but situated in the lungs of an ordinary patient, he can well defy us to attempt to drive him from that position. Inhalations do not go deep enough nor are they concentrated enough to effect much change. Experiments are being constantly made with this or that agent which kills or injures the bacillus, in the attenuated vapor to which it becomes reduced before it reaches his locality, with impunity of further effect upon the patient; but as yet we have no such drug on which we can rely.

Remembering that unfortunately there exists no specific curative remedy, we naturally seek for further means of prevention of the spread of this dread disease. I will only speak of two points in this connection. One is the importance of destroying the sputa, or at least its infectious properties, immediately on its expectoration. Have the material received in some vessel which contains a powerful parasiticide; or have it burned or buried at once. The second question is one which fascinates the medical profession; it is the endeavor to utilize our knowledge of the bacillus to render the system less susceptible to its deposition. Possibly this is to be accomplished by inoculation with attenuated tuberculous virus; on the principle that this would produce the same result that the virus of vaccine disease does in relation to small-pox. It is going to be a serious business if the future parent is to have his child inoculated with the virus of all infectious diseases, to preserve him from the course of diseases to which our present children are exposed. But if it is proved that each disease has its preventive inoculation, similar to small-pox, this may become a question which the parent of the future may be called upon to decide. At present we have no direct evidence that attenuated tuberculous virus will make the human species less susceptible; nor do I have much hope of such a possibility. Small-pox and phthisis are such different diseases that analogy between them is not striking; still many observers throughout the medical world are working over this point, on the lower animals, and we shall probably hear their conclusions in the future.

Undoubtedly there is a preparation of the system before the successful deposition of the bacillus takes place. Depressing influences have been at work; possibly some local catarrhal affection exists in the lung. The disease attacks only those who are not at the best state of resistance, while small-pox on the other hand attacks the strong and weak alike, another point of difference in analogy. Prevent this susceptible condition by increasing the vigor and resisting power, first by hygiene, secondly by attention to the digestion and assimilation. Often the remedies or treatment for atonic or irritative dyspepsia may be indicated. Keep this thought uppermost; that the digestion must be kept in the best possible state; if you do not injure it by the use of additional nutrients, try such things as fat, in cod-liver oil, plain or emulsified; but the oil will do no good unless it is well borne. At least as much food must be taken during its continuance as before its commencement. The amount must be decided by the patient; a teaspoonful that is pleasant is better than two teaspoonfuls that nauseate. But if a

tablespoonful can be well borne at a dose so much the better. If other preparations prove offensive, try the oil in combination with an alkaline salt, as the hypophosphites or lactophosphate of calcium; this introduces an element of nutrition which also favors the liquifaction of expectoration. Again cod-liver oil with wild-cherry bark suits many delicate or fastidious stomachs; here is a tonic and soothing expectorant at the one time. The markets are filled with preparations of this oil in combination with almost every known substance. Many of them are honest. I prefer those with lime as expectorants; with a tonic or with some digestive agent.

Iron is indicated in many cases, but frequently its use is attended with disappointment. If it serves to lessen the food-taking powers of the patient stop it at once. Often where cod-liver oil is badly borne iron is of service and *vice versa*, cod-liver oil may replace iron nicely.

Always make a study of the temperature in every case. It often happens that it must be checked. The best means of doing this vary; it depends on the condition which is making the temperature high. If there is active irritation around the seat of disease, not merely the infective poison of the system, but an acute catarrhal inflammation with exacerbations of temperature, this is best treated as an attack of catarrhal pneumonia. Rest in bed, counter-irritation, mild sedatives and antipyretics should be strictly adhered to until the temperature comes down. Antipyretics should never be given and the patient still allowed to go about; it is not philosophy or common sense. If the temperature is kept down with these drugs and the patient goes about, he is still more exposed to the causes which have produced the rise of temperature. If the inflammation cannot be removed, but there are occasional exacerbations when the patient is acutely sick, restrict the diet and apply dry cups over the seat of the morbid process. Where the fever is continuous, with no acute exacerbations, but still is rather high, antipyretics may be included cautiously in the regular treatment. Quinine can be used, provided it does good in moderate doses; that is, distinctly checks the temperature, when four, six or even eight grains a day are given. Under these circumstances there is no harm in continuing it for weeks at a time. Very small doses of antipyrin with quinine often produce marked benefit. Sufficient of this drug should not be given to produce a lowering of temperature within an hour or so, for although we know the power of these newer drugs to produce a lowering of temperature and nothing else, still under the use of antipyrin, I have always found the patient a little relaxed and a little more liable to catch cold than he was before. Hence only endeavor to check temperature slightly with such drugs; three grains of antipyrin with two of quinine twice a day are often excellent. Remember that inflammation is producing the fever, and that in keeping the surface temperature down too much, you may be injuring the condition of the patient. Relieve the temperature by hygiene, by diet, by exercise and by fresh air. Aconite given late in the day may be excellent; a single drop every hour for from five to eight hours, while producing no depression or relaxation, may be of inestimable service. Cool water externally, with its effects carefully studied, may be tried. A cool bath daily, and followed by friction is useful in some cases.

The cough nearly always requires attention. Usually it is poor judgment to attempt to stop it while the disease lasts; and after spots of broken-down tissue appear in the lung it is far better that it should not be checked. When, however, it is evident that there is a needless amount of effort expended by the patient; when he is racked by excessive paroxysms, then it should be controlled. The use of inhalations for this purpose is far better than the use of drugs by the stomach; for it is necessary to blunt the nerves of respiration, and the drug which does this, also affects the sensibility of the digestive tract; hence it is apt to impair the appetite. Use a sedative, antiseptic, alterative inhalation, which, while not strong enough to disinfect the lungs, fills the bronchial tubes with purified, disinfecting air. This does good while it relieves the troublesome symptom. Creasote, turpentine, terebene—a more volatile derivative of turpentine—preparations of iodine, chloroform, ether, conium, are all local sedatives capable of producing the proper results. The forms of apparatus for inhalation are legion. I prefer a simple jar, with ample cork; through the cork insert two tubes, have the material to be used placed in the jar and allow the patient to draw air through the shorter tube. This apparatus can be made into a portable form by using short bent tubes, corked at each end, in which is placed sufficient of the preparation for one dose. A

number of these tubes can be carried in the pocket; when the patient feels that a spell of coughing is coming on, he can open a tube and inhale its contents. A fair prescription for this purpose is the following:

℞ Creasoti . . . . . f℥i
Tr. iodi . . . . . f℥iii
Chloroformi . . . . . f℥ii
Alcoholis . . . . . q. s. ad. f℥i
Sig. Inhale ten drops.

Carbolic acid can be substituted for the creasote in somewhat smaller doses. Thymol, a highly volatile antiseptic, agreeable in odor, can be tried; tincture of conium can replace the chloroform; these are merely suggestions for your own improving. Ammonia developed by the action of a weak acid on the carbonate of ammonia makes a useful form of inhalation; to this you can add any volatile substance you think indicated. If there is excess of secretion, you can employ some astringent, such as zinc. In time, as your practice grows, you can call in, if you think advisable, the use of compressed air to drive these inhalations farther into the lung substance.

Occasionally, for a variety of reasons, you feel called upon to prescribe a cough mixture; the inhalations may be of no service, or inconvenient, or inaccessible to the patient's use. Then remember the cardinal rule of prescribing, that nothing shall be given that impairs the appetite. Use the simplest expectorants in the smallest possible doses. Given in syrup form, the expectorants are apt to be somewhat nauseating. I prefer some such pill as the following, which relieves cardiac excitement in case of fever, is rather expectorant, and allays irritation.

℞ Ext. opii . . . . . gr. iii–v
Pulv. digitalis . . . . . gr. xv–xxx
Pulv. scillæ. . . . . gr. xv–xxx
Quiniæ sulph. . . . . gr. xxx
Div. in pil. No. xxx. Sig.: one, two to four times a day.

If the squills nauseates, it can be subsequently left out. In place of the opium if it is found to be too constipating codeia can be given. Ammonium carbonate or muriate in simple brown mixture is excellent when the expectoration is thick and scanty. It makes an agreeable sedative and laxative.

Some cases admit of the application of remedies direct to the diseased spot. When the process is limited to one apex, remaining obstinately there: neither spreading nor shrinking and the patient is in good general health, it is admissible to insert into this circumscribed area by means of the hypodermic needle certain remedies. Creasote, thymol, iodine in small amounts at regular periods may relieve the symptoms most markedly. It is not a radical measure; there are no complications; expectoration is allayed. Irritation apparently subdued and general good results follow. Unfortunately the cases are rare which admit of this treatment; the process must be sharply circumscribed, easy of access and the injections must be rather weak and frequently repeated.

In a certain group of cases, creasote is well borne by the mucous membrane of the stomach; here it can be used for its constitutional effect; combined with the oil of eucalyptus in capsules it is often excellent. Constitutional treatment which will favor the appetite, be antiseptic and help to render the lung a less favorable nidus for the bacillus, can all be added in one prescription, such as the following, which is not unpleasant to take.

℞ Creasote . . . . . 32 drops
Comp. tincture of gentian . . . . 1 fl. ounce
Comp. tincture of nux vomica . . 2 fl. drachms
Whiskey or brandy . . . . . 2 fl. ounces
Glycerine . . . . . 1 fl. ounce
Sherry wine . . . . . 1 pint
M. S. Dose: a dessertspoonful to two tablespoonfuls.

This lecture I have intended rather as a hasty glance at a great subject than a careful discussion, complete in its details.

COMMUNICATIONS.

HYDROPHOBIA.

BY HIRAM CORSON, M. D.,
CONSHOHOCKEN, PA.

Hydrophobia is a disease which has attracted much attention, and is at present one about which opposite opinions are held. Some persons deny that it ever exists in the human system, while others, as M. Pasteur and his followers, believe that human beings are as readily and fatally affected when bitten by a rabid dog, as another dog would be if bitten. Not only so, but that, by inserting a portion of the brain or spinal marrow, taken from a rabid dog, into the body of a human being—as is done in inoculating with small-pox virus—persons may be protected from rabies. Such protection is offered to all at

the "Pasteur Institute" in Paris; and now, persons if bitten by a dog supposed to be mad, resort to this means of safety. In New York, too, such an Institute has been gotten up, and persons who chance to be bitten, even by a healthy dog, flock to the "Gibier Institute" for protection; for the opinion has been advanced, by those "cultivating" the virus and the fears of the public, that rabies may accrue from the bite of a dog not rabid, and that "even a rabid dog may communicate it to others and afterwards return to his normal state of health." And yet more, Dr. Gibier says: "I have experimentally demonstrated that birds, and notably hens, which contract rabies, may communicate it to mammifera, to which it will prove fatal, though the hens may spontaneously recover." Strange talk this by a man who writes: "I know of no authentic case of rabies that has been cured in man." The hen, though, has rabies, communicates it to a man, or cow, or horse, to which it proves fatal, but the hen, without the aid of the Gibier Institute, recovers.

It is not my intention in this paper to call in question the practice instituted by M. Pasteur, but to refer to the great increase of reputed hydrophobia cases since he commenced to inoculate persons in order to protect them. No one who has read of his practice and its results but must have been forcibly impressed by two facts: first, that reputed cases of rabies have astonishingly increased since he commenced his preventive and curative operations; and, second, that deaths from the disease, or its treatment in the hands of inoculators, are greatly in excess of the mortality prior to that time.

In the MEDICAL AND SURGICAL REPORTER, July 5, 1890, page 24, it is stated, "Of persons treated in the Pasteur Institute from May 1, 1888, to May 1, 1889, there were 13 deaths, or one death for every 128 treated."

It may be interesting to turn from the doings of M. Pasteur, and to inquire what is known of hydrophobia in our own country. There exists in the mind of all classes of people, everywhere in this country, great dread of mad dogs and of hydrophobia; a dread engendered and spread abroad by the newspaper reports of the horrible sufferings of the victims of hydrophobia; their convulsions at the sight of water or on attempts to swallow it; the distortions of face; the whining, howling and slavering, like dogs; and their being smothered under feather-beds, or bled to death to prevent them from injuring others.

On October 18, the newspapers reported that a man in Atlanta, Georgia, was so violent while under the disease, "that six men could not hold him down under a bed, but when eight men got on it, they were enabled to overcome him"—which meant smothering him, I suppose. Reports of bleeding such patients to death have been common from my earliest recollection. These things are known to every child of ten years; and is it strange, then, that the disease is regarded with peculiar horror?

When quite young—seventy years ago—a lad whom I knew "died mad," the people said. He had been bitten by a neighbor's dog which was immediately killed. It affected me greatly; so after my graduation in 1828, I applied to that museum of knowledge, Prof. John Redman Coxe, for information in regard to this disease, and from that time to the present I have been mindful of it. Prof. Coxe told me of the many kinds of creatures liable to the disease—hens were included—but the wise old man did not then know that a hen could have the disease, could infect other animals—even man, and then rid herself of it, and become food for rich citizens. That was reserved for our "Institute" to discover.

Mad dogs are not often met with in our State, or if they are, and persons are frequently bitten by them, then either the virus is nearly harmless in the human being, or we have better means of prevention than M. Pasteur's inoculation measures.

Why do I hold this opinion? Because during seventy years, with my eyes and ears wide open to see and hear all that is known on the subject, there is no record of a single well authenticated case of hydrophobia having occurred within our county, and only two supposed cases—cases of false hydrophobia perhaps—though many hundreds have been bitten by dogs said to be mad, during that period of time. If so many were bitten, how did they escape, when there was no Pasteur or Gibier to inoculate them? During nearly the whole of the present century, though the disease has not received any attention from medical teachers in our medical colleges, yet intelligent physicians throughout the State, acquainted with the teachings and experience of the justly celebrated English veterinary surgeon Youatt, practiced his teaching, and when persons who had been bitten presented themselves,

excised or cauterized the wounded part, assured the patient that he was in no danger, and no bad results followed. But physicians were seldom asked to prescribe for such patients. There were specialists then as now.

For more than a century there has been known, in the eastern part of Pennsylvania, two mad-dog doctors, to whom hundreds of people, bitten by dogs supposed to be rabid, have resorted for protection from hydrophobia.

"Dr. Stoy's Remedy for Hydrophobia" was known in the latter part of the last century, it is said, throughout Pennsylvania and in parts of the adjoining States, and was regarded as a certain preventive of hydrophobia. The following history was given to me a few years ago, by a friend. "Dr. Wm. Stoy was a native of Germany, who came to this country before the year 1800, and settled in Dauphin County, Pa. He devoted much of his time to the study of chemistry. Soon after his arrival he petitioned Congress for the grant of a large sum of money, on condition that he should promulgate his great discovery, for the cure of hydrophobia, for the public benefit. Failing in this, he then offered his recipe to the heads of families at a fixed price, binding them, however, under oath not to divulge the secret, or to use it for the benefit of others. After his death in 1809, his widow Elizabeth Stoy, took out a patent for this medicine. One who bought a "right" kept his oath so religiously that he allowed a neighbor who had been bitten by a rabid dog to die rather than violate his oath. Among the papers of one who had purchased the recipe, it was found after his death, written in German. It was translated into English, and is as follows.

"Take one handful of dried Anagallis Arvensis;[1] pour on it two quarts of good beer in an earthen pot; boil it over a slow fire to half the volume; strain through a cloth; add of vermilion treacle two drachms. It must be well stirred up and mixed in liquor. Dose for a man, one pint, to be taken in the morning, fasting. If any signs of hydrophobia appear, the medicine should be taken two or three mornings in succession. The dose for a female, three to three and one-half gills, for children according to age." Many years ago the following was published.

"MAD DOGS.—THE STOY REMEDY."

"In 1819, one Valentine Kectering, of Dauphin County, communicated to the Senate of Pennsylvania a sure remedy for the bite of any mad animal. His ancestors had used it in Germany two hundred and fifty-six years ago, and he had always found it to answer the purpose during a residence in the United States, of fifty years. He only published it from motives of humanity. This remedy consists in the weed called chick-weed—a summer plant, called by Germans and Swiss, Gauchnell Rother Mayor, or Rother Huehnerdarm, in England called Red Pimpernel; botanical name, *Angelica Phœnicia*. It must be gathered when in full bloom, in June, dried in the shade and pulverized. Dose for a grown person is a teaspoonful (in weight a drachm and a scruple) at once, in beer or water. For children, the dose is the same, but must be applied at three different times. It can also be put on bread and butter, or given in honey or molasses. The Rev. Mr. Muhlenberg said that in Germany thirty grains of this powder are given four times the first day; then once a day for a week; while at the same time the part is washed out with a decoction of the weed, and the powder strewed on it. Mr. Kectering said, that he, in all instances, gave but one dose with the most happy results. This is said to be the same remedy through which the late Dr. William Stoy effected so many cures."

I may remark here that he speaks of the plant as Angelica Phœnicia; while in Stoy's recipe it is spoken of as the *Anagallis Arvensis*, which is the botanical name of the red pimpernels. They evidently used the same plant.

During the long time in which Stoy and others used this remedy another man, or rather family, in Montgomery County, were celebrated as "mad-dog doctors." "Dr. Fry," the great mad-dog doctor, was a familiar name to me full seventy years ago; and as hundreds of people in this and adjoining counties have resorted to them for protection and cure, and always, it is reported, with success, allow me to speak of them. Even within my circle of practice many people have gone to him, and not a single one was a victim to the dreaded disease. As many of the persons were members of families with whom I practiced, I had frequent opportunities to see the printed directions, which are as follows.

"First wash the bite of the dog with warm

[1] This is the common pimpernel.—ED. REPORTER.

vinegar; then apply the blister to reach a little over the sore; tie it up; let the blister lay on for ten hours; when it has drawn a full blister, then open the blister and keep it off. Then take cabbage leaves and make them warm on the stove and soft in the hands; then apply them and let them lay on for two hours; then apply fresh leaves, and so continue till four days have expired; then apply the same blister again; let it lay on three or four hours; then take it off and dress with cabbage leaves, as before mentioned until fourteen days have expired; then spread a rag with sheep's tallow twice a day applied till it is healed."

"Medicine for hydrophobia. Take all this powder and put it in a new earthen pot; pour one pint of porter on it, and set the said pot on a low or moderate coal fire; let it boil down to one-half; then strain it through a clean linen cloth, hot out of the pot, into a pewter dish; then take the medicine out of the bottle and mix it well together, and when it is well united, then give to the patient one-fourth of the dose in the morning, fasting, lukewarm, and the remainder, the next four mornings in succession, as before mentioned, and the patient after taking each dose, must fast three hours, and fourteen days thereafter shall drink no water, not to meddle with water and not to see any water, and not to eat any pork or pies baked with lard, except butter, not to eat any fish or water-fowl that swims in water for fourteen days thereafter, and not to go in the rain or where it is foggy.—W. S. Fry; near Lansdale." "Dr. George S. Fry, Catharine Fry."

The above mode of treatment has been strictly followed by a great many people in our county and the adjoining ones.

Since Dr. Gibier opened his Institute in New York, and his reports have so excited the people's fears that cases of hydrophobia have greatly increased, I felt a desire to talk with our mad-dog doctor and learn from his own lips what his success has been. So, a few weeks since, I rode to Lansdale and visited him in his little store. When introduced to him by the friend who was with me, I said to him that I had come to see him in relation to his treatment of hydrophobia; the number treated by all the members of the Fry family, and their success in treatment. He quickly replied: "We never lost a single patient." "How many have you treated?" "More than three hundred." "Have you ever treated one when the disease was upon him?" "Yes! More than one, and they recovered." By this time he seemed to get a little suspicious that I had some secret motive for asking questions, and he became somewhat reserved. I then said to him: "I do not want to know anything about your remedies; and, to be frank with you, I have no belief in their possessing any medicinal value in preventing hydrophobia, but possibly great value, when conjoined with the assurance which you give the patient in removing the perturbed condition of the nervous system, and inspiring them with a firm assured hope —confidence I may say—of protection." This seemed to remove all reserve on his part. "Doctor, are you not in error in saying that you have never lost a patient, did not you lose young Yerkes?" "Ah! he died; but it was his own fault; the three boys were all bitten. The other two followed the directions for the whole fourteen days; but that young fellow, after being in the room two days, jumped out of the window and went to swim with neighbor's boys." The boy's uncle had told me that the boy had fully followed all directions, but I pressed Dr. Fry no further, but said to him: "I have been told that you use the same remedy that was used by Dr. Stoy—the red pimpernel." "Yes! we use *that;* but we have five other ingredients." He narrated a severe case of the disease to which his father had been called, and which he cured.

The readers of the REPORTER will doubtless ask, why I have thought it necessary to speak of the unscientific practice of these non-professional men, and especially as I do not believe their remedies have any medicinal effect of value in the treatment of the disease?

The object in treatment should be to prevent the occurrence of disease, and, if present, to cure it. It appears that many persons have lost their lives after treatment by Pasteur, yet he boasts of great success. From his own statement, one out of every one hundred and twenty-eight died, but the *Journal de Médecine*, March 30, contains a list of ninety cases who have died after receiving the so-called "preventive treatment." In addition to that, it is said to be a fact, that since it has been practiced, there has been an actual increase in the number of deaths from hydrophobia in France. And a similar increase is said to have been noted in New York as a result of the excite-

ment caused by the existence of the Institute there.

Now, everywhere in this State the confidence of the masses in the power of the mad-dog doctors seems to be so great, that even when bitten by a dog supposed to be rabid, their nervous systems are not so disturbed as to lead to fatal results. Dr. Fry says that out of more than three hundred who were bitten and treated by him, not one was lost by hydrophobia, after their treatment. Pasteur has lost many—Fry not one; or, if any, only one. It is seventy years since the little boy, Rossiter, died from what was called hydrophobia; and I do not know that he received Fry's treatment. I know of no other one in all these years, anywhere in the county—though scores have been bitten—who died from rabies, whether treated by Fry, or by physicians, or not treated at all.

I wish to be fair towards the Pasteur Institute, and therefore regret that I have not access to their reports up to this time. In the MEDICAL AND SURGICAL REPORTER of October 25, 1890, which has just come to me, I find "Hydrophobia Notes," from which I gather that a patient died in the Bellevue Hospital with his arms tied to the side of the bed and four men holding him, while the physician dosed him with morphia and gave him chloral. Gibier says it was a genuine case of hydrophobia. I have no knowledge of the case save this. Whether the man was bitten at all, and what the symptoms were which made it necessary to tie him to the bed and have four men to hold him, I do not know; but I do know that the physicians of that hospital should not have allowed such a report to be sent abroad, through the newspapers, and even Dr. Gibier's declaration that it was a true case of hydrophobia may be honestly questioned by those who are well read in the history of hydrophobia. In the August number of the *North American Review*, there is a paper on "False Hydrophobia," by Dr. Wm. A. Hammond, Surgeon-General, U. S. Army (retired), in which, on pages 170 and 171, he writes, "Several years ago I saw, in consultation, a policeman who had two or three days before been bitten by a dog, and whose comrades had frightened him by their inquiries and suggestions. He was then in the Park Hospital, in the city of New York, held down by four strong men, and snapping like a dog at every one who came near him. At the sight of water, he became intensely excited, and went through a series of fearful contortions of his face. He had visions of mad dogs trying to bite him, and was hiding his face under the bed-clothes. Every attempt to make him drink a glass of water produced a series of spasms and howls of anguish that alarmed the neighborhood. The short period of the incubation, the extreme violence of the symptoms, and the fact that he had drunk a glass or two of brandy without difficulty, gave me at once a clear idea of the case. I filled a tumbler with ice-cold water and holding it to his lips told him in a commanding tone to drink it immediately. He took the tumbler in his hand and drank it as readily as he had ever done in his life. The spell was broken, and a few minutes afterwards he got out of bed declaring that he was perfectly well, and he went to duty the next morning. It is quite within the limits of probability that if he had been allowed to go on for two or three days in the way he had begun, death from exhaustion would have been the consequence.

"That death may result from false hydrophobia is as well established as any other fact in medical science. There is a case on record of a man who died in fifteen hours with all the symptoms of hydrophobia which had ensued on a violent paroxysm of anger."

Dr. Hammond gives other most interesting cases of false hydrophobia, which I must leave for the present, but which ought to be known to all physicians, so that when standing by the bedside of such a patient they should not require the man to be bound to the bed and have strong men to sit on him, or smother him under the bed; but should be able to distinguish the false hydrophobia from the true—if there be a true—and use means to cure him. And let me add here, that whenever the patient exhibits very violent symptoms, it is almost positive proof that it is the false kind. I have received from my friend and neighbor, Dr. Oscar Leedom, an account of a case to which he was called a few years since, which may be interesting to practitioners.

"I was called one evening in the fall of 1882 to see a young man supposed to be suffering with hydrophobia. Upon arriving at the house I found the family in a great state of excitement. His mother, an intelligent and honest woman, told me that he had been bitten by a dog a short time before, and that she feared he was getting hydrophobia. I allayed her fears as much as possible, and asked to see the patient. I

found a young man of twenty-five years in a dark room, while two strong neighbors were holding the door. At my request they opened it, when I found the patient going round and round the room on all fours, like a dog, and imitating a dog's gait and antics as nearly as possible. He continued this for some time, then suddenly darted out of the room to an adjoining one, still going on his hands and feet. I then had him caught and held by the two men, while I assured him that he had no hydrophobia whatever, and that he must quit his antics, or I would have him held under the pump and have the cold water pumped on him. This quieted him somewhat, but on releasing him he darted off again, into the back room, and began to go round on his hands and feet, dog-like, again. I then had the two men to seize him and drag him into the kitchen where stood the pump, where I determined to pump water upon him. This brought him to his senses, and he begged us to let him go. I told him I would only let him off, on his promise to do as I bid him. To this he agreed. I then gave him one-quarter grain of sulphate of morphia, and told him to go to bed. He swallowed the medicine, and then hurried up stairs to bed. There was no more trouble with him that night, and next morning he was well and ready for work. So ended my case."

How applicable here are the remarks made by Dr. Hammond in closing his case: "If this man had been allowed to go on for two or three days as he had begun, that death from exhaustion would have been the consequence." Suppose that Dr. Leedom, instead of assuming a tone of authority and determination, had, as seems to be the usual custom with physicians, been afraid to go near to the patient, had gotten some one to get a cup of water—after he had him secured—and had asked him to drink it; would he not have shrunk from it, have been thrown into spasms as is so usual in such cases, and it have resulted in his death?

As we have looked somewhat into the doings of the Paris Institute, let us turn our attention to Dr. Gibier's Institute in New York. In the MEDICAL AND SURGICAL REPORTER it is stated that thirty-nine persons were bitten by animals supposed to be rabid; that many of the animals were not known to be rabid; indeed there was not a single case known to be so. That those who were bitten were badly frightened people who had heard of Pasteur's treatment is apparent from the fact that many of them came from far away States. In the cases of the boy of twelve years, bitten two weeks before he reached the Gibier Institute, and the old man of 70, bitten twenty-eight days previous to reaching there, Dr. Gibier refused to treat them. Why? Fearing, we may believe, that the incubation period was nearly completed and that, if so, his remedy might fail and thus be discredited. So, instead of inoculating them—a most fortunate escape for them—he pronounced them doomed; yet they remained well. But suppose instead of refusing to treat them, he had inoculated them, and they had gone home and remained well; then they would have swelled the lists of cures, as hundreds of others like them have done. It is apparent that his confidence in his means of prevention is very weak. As for curing one already "mad," he makes no pretense to do that, but honestly says, he "has never known a case of rabies to be cured."

In the August number of the *North American Review* in a paper entitled: "The Pasteur Treatment," by Dr. Paul Gibier, Director of the Pasteur Institute in New York, he writes: "Some die fifteen or twenty days after having been bitten, others only after a few months or even years." Dr. Hammond in the same number of that Review, in a paper on "False Hydrophobia," says: "Hydrophobia rarely supervenes until after a month has elapsed after the bite; and in my cases the time has varied from twenty-five days to four months." With these facts before him, and the testimony of the celebrated and experienced veterinary surgeon Youatt, that "the excision of the wounded part, at any time prior to the attack of rabies, would insure the safety of the person," that Dr. Gibier should have refused to treat them, and to declare that they were doomed, is not readily explained, save by the theory that he had no confidence in his means of prevention. Now let us consider what has taken place all over our country in relation to persons bitten by dogs—I will not say mad dogs—as rabid as were those by whom Dr. Gibier's patients were bitten. In the country nearly every family keeps a dog; many families two or more, and country physicians are very liable to be bitten. It has been my fate many times—three times in one week I was attacked, and two of the bites received drew blood from me. So it was no doubt with hundreds of others in this State. But we did not kiss the mad-

stone, or go to the mad-dog doctors, and fortunately we had no "Institute" where we could be inoculated, so we just went on as though nothing had occurred, or as though we had never heard of danger from the bite of a dog; and yet who ever heard of the death of a country doctor from the disease called rabies? There have been thousands of persons bitten by dogs in Pennsylvania during my seventy years of observation, in relation to cases of rabies; and yet, how very few deaths from hydrophobia, true or false, have we heard of. How shall we explain this, seeing as we now do, that hundreds, yea thousands, are flocking to the Institutes, in New York and Paris, who have been bitten by mad dogs—or by healthly dogs—whose bite is, according to Dr. Gibier, capable of causing rabies in mammifera, save by saying that mad dogs are very scarce; that bites of healthy dogs cannot cause rabies; that no such case has ever occurred; and that, here, when a person was bitten by a dog and feared that he was rabid, he went at once to a physician and had the wound excised or to Dr. Stoy, who, according to the report of Kectering, used a remedy which had been successful in every case during two hundred and fifty-six years, or to Dr. Fry, who, in hundreds of cases treated by him, had never lost one, or only one.

These were the means used by many, and yet not by one-tenth of those bitten; the great majority did nothing, but like the country doctors, gave themselves no trouble about it.

But let us look into Dr. Fry's "Institute." In it we see, not thirty-nine, but three hundred or more, men, women and children, who have been bitten by dogs (I will not say rabid dogs—as rabid, though, as were the dogs by which Dr. Gibier's patients were bitten), and whose fears have brought them to this unscientific man, of whose great power to save them they have often heard. They came with strong faith that as soon as they were under his treatment they would be safe. He does not terrify them—turns none away through fear that they may have nearly reached the end of the incubation period, but with a strong confidence in his measures, begotten by a half century's unvarying success, inspires them with a joyous hope and from under his hands they pass away relieved from fear and protected, one and all, from the dreaded rabies.

And, now, what has been the outcome in all Pennsylvania to those who took no measures to protect themselves, others who sought relief from physicians, and those who trusted themselves to the mad-dog doctors, Stoy and Fry? I answer, as I think physicians throughout the State will, that we have scarcely had a well-authenticated case of true rabies in all this populous State. But alongside of what has happened here, how frightful are the reports which come to us of deaths under the inoculation measures in Paris. Do I believe that because Fry and Stoy lost none and Pasteur many, very many, by death, that the medicine given by the former, and the apparently absurd precautions and course of diet and conduct prescribed by him were necessary? I believe the medicine, and all else advised, were entirely useless, save only as they served to allay the fears of the patients and confirmed them in a belief of their own safety. If, then, my opinion is correct, that the medicine had no value as an antidote to the poison of rabies, it must be plain to my readers that the dogs—the hundreds said to be mad—were not so; and this is the reason why the hundreds—thousands of persons, I might say—bitten by dogs in Pennsylvania during the past century did not become victims to true hydrophobia, though a few may have fallen victims to false hydrophobia—an affection so ably described by Dr. Hammond, who is the peer of physicians of the "Institutes" in this or any other country.

I believe there is a disease called rabies, to which dogs are liable, and I always heretofore *have* believed that it could, by the bite of a rabid dog, be communicated to the human system; but now it seems as though false hydrophobia may yet include all cases which may happen in human beings. Time and more careful observations than have heretofore been made will soon reach the truth in this matter. Until then I hope that physicians will earnestly investigate the subject, and that all medical colleges will have it embodied in their course on the "Practice of Medicine," and that Pennsylvania will be saved from the dangers which would follow the erection of a Pasteur Institute within her borders.

It is said the mark of weak medical men is the indiscriminate use of stimulants in fevers, a ready resort to narcotics and sedatives, treatment of symptoms only and a fondness for new drugs and high-sounding names.

ATMOSPHERIC TRACTOR.

A NEW INSTRUMENT, AND SOME NEW THEORIES IN OBSTETRICS.[1]

BY PETER McCAHEY, M. D.,

PHILADELPHIA.

On December 20, 1848, and February 7, 1849, Professor J. Y. Simpson, of Edinburgh, described before the Obstetric and Medico-Chirurgical Societies of that city, a device for assisting labor which he termed an Air-Tractor. In its first form it consisted of an ordinary metallic vaginal speculum, fitted with a piston and coated with leather at its cone-shaped end. This was finally discarded for a short brass syringe attached to an inner cup of horn, which was covered with an outer cup of rubber. The mouth of the inner cup was covered with a diaphragm of wire, within which was a piece of sponge or flannel, "with the view of preventing injury to the scalp and not allowing it to be elongated and drawn up into the vacuous space in the manner which we see occurring in the skin in the common operation of cupping. Such an instrument when fixed to the palm of the hand lifted readily a weight of thirty or forty pounds. This Dr. Simpson showed by experiments before this society." (Simpson's *Obstetric Memoirs:* Philadelphia, 1855.)

Professor Simpson in his eloquent and thoughtful manner pointed out the dangers incidental to prolonged labor and also to the use of the forceps, and declared his belief that the air-tractor would eventually prove a substitute for them in many cases. He explained the well-known principle of atmospheric pressure upon which it was based, and referred to the many instances in which the same principle is employed by the lower animals, such as the leech, the limpet and the cuttle-fish, to secure their food or to move about. He added that while the Tractor had been used in several cases "with results answering his best expectations, it admitted of much further improvement in construction, in mode of application, in working and in other details."

Unfortunately for humanity, it did not work, and was finally abandoned by its gifted inventor. So complete was its failure that, although Dr. Simpson lived until 1855, he did not publish any more in reference to it, nor is it mentioned even as a curiosity by any of his English or American contemporaries or successors.

Dr. Horatio R. Storer, the American editor of Professor Simpson's *Obstetric Memoirs*, stated in 1855 that "the chief objection to the practical use of the tractor is doubtless in its application, and not in its power of traction; the large size of the caoutchouc cup rendering difficult its introduction within the maternal passages. To this may be added the difficulty of keeping the valves in working order. Dr. Simpson, however, holds, and we believe, correctly, that if ingenuity could suggest any form of tractor which umbrella-like should be folded into a little space for introduction and afterwards expanded over the scalp and then exhausted by the attached piston, it might supersede the forceps in many cases. . . . When we revert to the history of some of our most useful obstetric instruments (contrast, for example, the rude form of the early forceps with their present improved construction), we have reason to hope that the tractor may at some future time be so far improved as to be easily applied and used."

Dr. Simpson's tractor failed partly because of the difficulty of working an air-pump within the vaginal canal, and partly because of defects in the construction of the cup.

If I had read of his failure, I would probably have considered it hopeless to try further experiments in the same direction.

In common with a great number of others, I had not heard or read of them until after I had, as the result of independent inquiry and over five years of study and experiments, constructed a new and entirely practicable Atmospheric Tractor. On learning a few weeks ago of Dr. Simpson's efforts, I was at first disappointed to find that I was not, as I had supposed, the first to suggest its use. After further consideration, however, I think it will be admitted to be as great an honor to have succeeded where so brilliant an obstetrician and so able a man as Professor Simpson failed, as to have evolved the original idea.

I began the study of the subject in 1885, in the hope of finding some means of preventing the annoying retrocession of the head. I at first endeavored to secure this by a modification of the old abdominal bandage; but the forces driving the head back were stronger than any power that could be exerted with the bandage. This

[1] Report of a demonstration before the Philadelphia County Medical Society, November 26, 1890.

led me to think that there must be some other agency producing the retrocession besides muscular resistance and bony rigidity. No doubt every physician has observed many cases in which the head retroceded, not only before the pelvic muscles could act, but even before it reached the pelvic floor. Further reflection and observation led me to the conclusion that atmospheric resistance is the principal factor in producing this retrocession and is in many cases a potent factor in delaying delivery.

When the uterus contracts round the body of the child, it expels all or nearly all the air from the uterine cavity, just as, when the hand firmly grasps a ball, the air is squeezed out from between it and the palm and fingers. The abdominal muscles then contract, forcing the fundus of the uterus down and pushing the child's body and head into the pelvic cavity. While this is occurring, there is a partial vacuum in the upper part of the uterus or that portion of it which is firmly contracted around the child. When the abdominal muscles relax, the pressure of the external air, and the expansive pressure of the air in the vagina are exerted against the head and shoulders of the child, and force it back until sufficient air enters the uterus to overcome or break up the vacuum and elevate the fundus. A similar process can be observed every day in the use of the ordinary ball-valve cupping apparatus. Pressure on the top of the ball drives out a certain quantity of air from the cup, but in a moment or two the expansive pressure of the remaining air forces the ball into its usual globular shape. The advantageous results which have been obtained by moving the forceps from side to side in cases where extraction is difficult, can readily be accounted for when it is realized that such motion permits the free ingress of air from the vagina and breaks up the uterine vacuum.

That the retrocession of the head is due to atmospheric pressure almost altogether and only in a small degree to muscular resistance or pelvic rigidity, must be obvious to those who have felt the head stop and recede before it had reached the pelvic floor and while it was still suspended in space, a half an inch or more above the muscles.

Professor Duncan (Duncan's *Obstetric Essays*), who must have frequently noticed this apparent anomaly, realized the inadequacy of the commonly accepted theories on the subject, and ascribed the retrocession in such cases to the "retentivity of the abdomen," but failed to perceive that this retentivity is almost entirely the result of atmospheric pressure.

Being convinced that atmospheric pressure is one of the principal causes of delayed labor, and knowing that there is nothing more easily displaceable than air, I began to work upon the problem of how to lessen or remove it during labor. I am convinced that I have succeeded and that the atmospheric tractor which I have the honor to demonstrate before you this evening will inaugurate a new era in the history and practice of the Obstetric Art. It will be, not only a substitute for the forceps in cases in which instrumental aid is absolutely necessary, but it will also be an indispensable assistant in cases which are usually left to the tedious and painful efforts of Nature. With it the physician can dispense with anæsthetics and reduce the expulsive stage of labor to a few minutes, instead of hours, the agony of child-birth will be reduced to an infinitesimal degree without incurring any risk or inflicting any injury on either the mother or the child, and many lives will be saved which would otherwise be lost.

The operation is extremely simple. It consists in applying a cup or concave disk of rubber or other air-tight flexible material, to the child's head, and creating a vacuum within or beneath, so that it will be firmly affixed to the head by atmospheric pressure, and then making traction on the handle of the cup or disk. Any amount of desired power can be obtained by employing a cup of sufficient area. The normal pressure of the atmosphere being fifteen pounds to the square inch, it is obvious that the tractile power capable of being exerted through a cup or disk of four square inches of area, and within or beneath which a vacuum has been formed, will be sixty pounds. The cup which I have here, covers when expanded a surface of about five square inches. If the vacuum beneath it were perfect and if the surface to which it is affixed were homogeneous, polished and solidly coherent, it would furnish a tractile force of almost seventy-five pounds. Allowing fifty per cent. for the loss of power consequent upon the elasticity of the cup, the flexible character of the scalp, and the mechanical impossibility of producing a complete vacuum, there will still be left a force of thirty-seven and a half pounds, which when properly applied is more than

sufficient to quickly and safely terminate any case of labor. It has been claimed that there are cases in which an enormous force is requisite, cases where the physician has been obliged to pull upon the forceps with all his force and even to ask an assistant to furnish additional power. Reflection will show, however, that in no such case has the physician exerted his entire muscular strength in endeavoring to extract the child. He may think he did, but he was involuntarily prevented from so doing, partly through the intuitive fear of injuring the mother or the child and partly by the expenditure of a considerable amount of his strength in maintaining his own equilibrium. Were a physician in any such case to exert his whole muscular force, he would pull patient and child out of the bed or haul both the bed and the patient around the room.

The large amount of force apparently required in some cases is because it is misdirected. The head is not properly flexed, and traction is exerted in a direction that would tend to pull the occiput through the pubic symphisis, instead of under the pubic arch, and it must be remembered that a great amount of force is unconsciously expended in maintaining the grip of the forceps on the child's head, especially if traction be made at the moment when the uterine vacuum is most complete. Experiment with any globular surface will show that unless increased pressure accompany the tractile efforts, the jaws of the forceps will be expanded and slip uselessly over the body that they were intended to move.

Scientific manipulation is the requisite in obstetrics, and not great force misapplied. If the occiput be lowered so that the head can revolve or pivot against and under the pubic arch, the voluntary or involuntary contraction of the child's posterior cervical muscles will be sufficient in many cases to throw the face upwards and outwards and facilitate or complete delivery. If the head be in a proper position for this final upward and outward rotary movement, comparatively little force is needed to complete delivery. Professor Duncan in his researches upon the power employed in labor arrived at the conclusion that "the maximum force in the most difficult labors does not exceed eighty pounds; that the great majority of labors are completed by the propelling force not exceeding forty pounds, and that in the easiest labors comparatively no force at all is exerted, the child gliding into the world by its own weight." An examination of his calculations will show that these estimates of eighty and forty pounds are much too high. He made the mistake of confounding the result of the force employed with the force itself. His experiments, briefly stated, consisted in fastening a series of sections of the amnion over a conical vessel, the mouth of which was about sixteen square inches in area. He connected this with a water-pipe of one inch in area and found that the amnions of minimum strength were ruptured when the pressure on the water in the pipe reached four ounces and those of maximum strength, when it reached three and one-tenth pounds. He then calculated that if the pressure on one square inch of the strongest membrane at the time of its rupture was three and one-tenth pounds, the pressure on the entire thirteen square inches of it, when the bag of waters was projecting through the os into the vagina, would be forty pounds. This was correct, but he erred in assuming that this forty pounds manifestation of pressure implied that there was forty pounds of force exerted to produce it. The laws of hydrodynamics and the laws of the multiplication of forces show that there is a very great disproportion between a force and its results or between the power exerted and the weight which that power will move. A force of one pound in the tube of the water bellows will lift one hundred pounds on its surface. A man with a crow-bar can move ten or fifteen tons. It may, therefore, be safely assumed that the bursting of the membranes under a pressure of three pounds to the square inch does not mean that there is a force of forty pounds or more exerted against the other end of the uterus. The proposition that eighty pounds of force is exerted in other cases as the result of muscular efforts is not much less extravagant than the assertion in *Tristram Shandy* that the force of the efforts in strong labor pains is equal upon an average to the weight of four hundred and seventy pounds, acting perpendicularly upon the head of the child. A force of eighty pounds applied to the body of an unborn infant weighing five or six pounds would be equivalent to a force of two thousand pounds applied to the body of an average adult—more than sufficient in either case to produce immediate death.

Exerted as a tractile force, eighty pounds of power will move a weight of four hun-

dred pounds, which is more than the usual weight of the bed, patient and child combined.

The problem in labor is to move a two-pound head two inches in one direction and eight or nine inches in another, through a channel, the walls of which are soft and yielding and covered with an unctuous secretion—conditions which reduce the element of friction to the lowest point. The occiput is only required to traverse the depth of the pubic symphisis, while the forehead and chin must traverse the entire depth of the pelvic cavity and extended perineum. It is obvious that the most rational way of accomplishing this complex movement is not to attempt to make the head advance as a whole, but to move one end first and then the other.

With the forceps the head must be moved more or less as a whole along the imaginary curve of Carus. With the forceps, practically nothing can be done but to pull. Rotation may be attempted, but in trying to perform it the points of the blades may, and often do, inflict serious injury upon the maternal tissues.

With the Atmospheric Tractor nothing is more easy than to apply it to the upper portion of the head and bring down the occiput. It may then be applied to the lower portion of the cranium, and the forehead and chin may be easily drawn upwards and outwards, and delivery completed. If the head is caught on the pubic bone, as in a semi-frontal or brow presentation, it can be easily pushed back with the tractor, and then depressed or rotated in any desired manner before being brought down. The tractor is practically a clamp which can be firmly attached to a large area of the surface, placing the head under the absolute control of the physician and enabling him to lift it, to turn it and to move it in any desired manner.

In order to apply it, all that is necessary is to see first that the os uteri is sufficiently dilated or dilatable to permit of its introduction. After having decided on the part of the head to which it is to be applied, place one hand against the abdominal projection, in order to prevent the head from receding, and introduce the tractor into the vagina or within the os, and firmly press it against the child's head until the handle or vacuum producer has driven out all the air from within the disk or cup. The handle can then be grasped, and extraction proceeded with. If, as occasionally happens, the head is dry, it ought to be moistened with water, or rubbed with some unctuous material.

The principal objections which may be urged against the use of the tractor are:

1. That the hair on the child's head will prevent it from being firmly applied.
2. That it is difficult to apply.
3. That its application will require injurious force.
4. That when applied it will exert injurious pressure.
5. That it will act as a cupping glass, producing an unsightly swelling, or even—as has been thoughtlessly asserted– "draw out the child's brains."
6. That in using it the scalp might be torn off.
7. It will carry infection.

The first of these objections I will dispose of by a practical illustration. (Dr. McCahey here affixed the tractor on the head of an infant three weeks old, and after moving it around a cot which had been provided for the purpose, lifted it up in the air two or three times, the tractor remaining in position all the time and the child apparently suffering no pain.) These, and other objections which may be raised, are based upon a misapprehension or a forgetfulness of the laws of hydro-dynamics.

As to the second objection, as you have just seen, the tractor is not difficult of application. As to the third, the amount of force necessary to create the desired vacuum is less than ten pounds at starting and decreases to almost nothing as the air is driven out of the cup, and it is exerted not on the head, but on the air within the cup.

The tractor cannot exert injurious pressure on the head. With it on the head there is no more pressure upon the area it covers than before it was applied. It merely takes the place of the lowest strata of air and is held against the scalp by the ordinary atmospheric pressure.

It will not act as a cupping glass, because it is applied flat against a large area, while a cupping glass is applied against a narrow circle, into which it is driven by the overlying air.

It will not produce an unsightly swelling, because there is no cavity into which an effusion can take place, and even if there were a large central opening, the brain would not be sucked up into it, because there is no internal pressure sufficiently

strong to force the brain either through or against the scalp. The tractor may be applied with absolute safety over either the bony part of the skull or over the fontanelles.

There is no danger of detaching the scalp because the tractor is not sewed or glued to the skin. It is affixed against it by a certain atmospheric pressure. Traction exerted in excess of that pressure will merely result in a separation of the disk from the scalp and not the tearing of the scalp from the bones. It can thus be seen that injurious or excessive force cannot be employed with it.

It is well to remember in this connection that while we speak of making traction on the head with the apparatus, and while we do apparently pull the head and lift the child with it, in reality we simply relieve the front of the head from the pressure of a five-inch cylindrical column of air, thereby allowing the head to be moved forward or the child to be lifted by the expansive force of the air behind or beneath it. No greater force of traction can possibly be excited by this apparatus because at the instant when it passes beyond eight or ten pounds to the square inch, it will separate from the head.

If the disk or cup were left on the head for a long time it might produce a slight congestion of the skin or even a small swelling, but nothing comparable to the caput succedaneum or the cephalhematoma sometimes occurring, which are the result of continuous pressure against the rigid os or the bony pelvis. Even if there were a slight discoloration or effusion, it would be certain to pass away in a few hours or days, and must not be allowed to weigh for one moment against the instantaneous relief from pain and the quick and safe delivery obtained by the employment of the tractor.

Pain is due to the resistance met with by muscular action. The resistance encountered by the abdominal muscles when pressing the head of the child against the bony pelvis is productive of intense pain. If the position of the head be changed with the tractor, and the abdominal muscles be relieved of the necessity of expelling the child, the pain ceases as if by magic.

The danger from infection is absolutely nil, if ordinary cleanliness be observed. After using the tractor all that is necessary to purify it for the next case, is to place it for a few minutes in boiling water or any antiseptic solution.

I have constructed various forms of tractors, some with a ball-valve, some with an air-cock, to which a rubber tube three or four feet long was attached, and an air-pump adjusted at the other end of the tube so that the nurse or other attendant could readily produce the desired vacuum, some with curved edges, some with concave edges; but the form I have exhibited to-night is the most readily applicable and the most reliable and best. As you see, it flattens itself out when applied to the head, thus giving an area of contact and traction equal to its entire surface. With the other forms, traction and contact can be obtained only within a limited area around the circumference.

The cups in which the air is exhausted by means of a pump or a ball-valve are open to the serious objection that their valves would become clogged up with the material on the child's head, which would require that they should be taken apart and cleaned or discarded entirely after each case.

I have used the Tractor in five cases, and in each case effected delivery with it in five minutes. Without it labor would have been prolonged in all for hours—hours of suffering to the mothers and hours of more or less anxiety to the attendant. An instrument capable of producing such beneficial results is certain to be universally employed within a comparatively brief period.

PERISCOPE.

Posthumous Labor.

In connection with the item on posthumous labor, in the REPORTER, October 4 and November 1, we quote the following letter of J. H. Nankivell, M. R. C. S., District Surgeon of the Transkei, South Africa, from the *Lancet*, October 18, 1890:—"In your issue of July 19 there is a notice of a reputed case of posthumous labor occurring at Moglia in the province of Mantua. In February, 1888, I made a post-mortem examination at mid-day on Sunday of the body of a woman who died before noon on the preceding Friday. After her death the friends sent four miles away to a shop for materials for a shroud, made the shroud, and put it on the body. On Saturday they put her into a coffin. On my arrival, in company with a magistrate, they informed me that the deceased died in the sixth or seventh month of pregnancy, and because

two or three weeks ago she had been assaulted they had reported the case to the magistrate. I opened the body in the usual way (as it lay in the coffin), and on passing my hand into the abdomen found no pregnant uterus. The astonishment of the relatives was great and evidently genuine. Upon further examination I found a large uncontracted uterus in the pelvis, and upon ripping open the remainder of the shroud, I discovered, lying under the thighs, a newly born dead child with cord and placenta attached. The friends were positive that the birth had not taken place when they lifted the body into the coffin, as from the way in which this was done two of them would have felt the child and the soiling of the shroud. Moreover, they assured me that at this time, about noon on Saturday, the corpse had an unpleasant odor and froth was oozing from the nose and mouth. When I had the lid removed in order to make my examination, there was not the least sign of the body having made any movement, ante- or post-mortem. But what struck me as strange (and the weather for two days had been cold, with drizzling rain) was that the temperature of the interior of the body was rather above than below normal. I could only come to the conclusion that the woman had died with a very high temperature from a fever which was at that time prevalent among the natives, and that the child had been expelled by the uterus certainly six hours, and in all probability more than twenty-four hours, after its mother's death. As the uterus resists decay longer than any other muscle in the body, so it may retain for a longer period after death its power of contraction. In such cases it is reasonable to suppose that the first and a portion of the second stages of labor are completed before death, and that the fetus and placenta are expelled either before rigor mortis has set in or after it has passed away."

Pennsylvania State Board of Health.

In his annual report Secretary Lee, of the Pennsylvania State Board of Health, says that the water supply of Philadelphia is the only one in the entire State, so far as he has been able to discover, which the Legislature has thought it worth while to protect. Influenza, he says, was the only widespread epidemic which visited the State during the year. Up to the last of May, 88,416 persons had been ill with the disease. Warning circulars were sent out during the year to clergymen and undertakers advising against holding public or church funerals in the case of persons who have died of contagious or infectious diseases. Small-pox appeared in but three cities—Pittsburgh, Canonsburg and Glenlyon, and only two cases of leprosy, one in Philadelphia and the other in Chester. Considerable complaint was heard during the year regarding the collections of stagnant water in the beds of abandoned canals.

As Superintendent of Vital Statistics, Dr. Lee has issued the first official "Register of Physicians in Pennsylvania by Counties," a volume of 425 pages, giving the date of registration, full name, sex, place of birth, residence, etc. The Secretary says there are many names recorded of persons holding diplomas from those infamous bogus faculties which disgraced Philadelphia some years since.

The total number of graduated physicians registered is 7,315. Of the 8,248 reported 641 are of foreign birth. The registration indicates that 7,316 are graduates of medical colleges, 2,009 being among the Alumni of Jefferson Medical College, and 1,945 among the Alumni of the University of Pennsylvania. The returns show that there are 952 physicians practicing without diplomas. There are 316 female physicians in the State.

The report recommends legislation to prevent the pollution of streams and to provide for the sanitary organization of the State.

Sterility.

The Boston *Medical and Surgical Journal*, November 13, 1890, says:

A few months ago a French author told a story of a married pair who consulted him, as they wished to have children. They had just come from the office of a well-known Parisian physician who had advised that the wife's uterus be curetted. A thorough examination revealed nothing wrong with the woman, but the husband's spermatic fluid was found to be entirely without spermatozoa, due to a previous double epididymitis. That the common opinion, that failure to produce children is probably due to some defect in the wife, is not justified, is shown by Lier and Asche, who found that out of 227 cases of sterility 132 could be credited to the man, most of them due to previous gonorrhœa. Where the man was at fault

only six per cent. recovered their power of reproduction by treatment, whereas twenty-five per cent. of the women subsequently became pregnant. The authors emphasize the importance of examination of the spermatic fluid in all supposed cases of sterility.

Trional and Tetronal.

The supplement to the *British Medical Journal*, October 18, 1890, cites the *Deutsche med. Wochenschrift* as authority for the statement that the action of trional and tetronal has been tried by Drs. Barth and Rumpel. Both these bodies are related to sulphonal. Sulphonal is diethyl-sulphon-dimethyl-methane; trional is diethyl-sulphon-methyl-ethyl-methane; tetronal is diethyl-sulphon-diethyl-methane. Trional is therefore sulphonal in which one radical of ethyl replaces one of methyl. In tetronal both radicals of ethyl are replaced by ethyl. The action of these preparations was tested in cases in which sulphonal had been proved to have a beneficial effect. Tetronal was given 74 times in 30 cases, the largest individual dose being 60 grains. It was effective in 65 instances, and did not produce any disagreeable effects. Trional was given 72 times in 40 cases, and produced sleep in 64 instances, the largest individual dose being 45 grains. In some cases lassitude and drowsiness were complained of as after-effects. In 21 cases of delirium, tetronal was given 52 times, in 10 cases trional was given 52 times; neither had any appreciable effect. The authors conclude that both these hypnotics are useful drugs, but are not superior to sulphonal. In some cases in which sulphonal did not act trional and tetronal were effective, for example, in certain nervous conditions. Both drugs seem to have fewer after-effects than sulphonal.

Isococaine, a New Anæsthetic.

The *Pharmaceutical Record*, October 20, 1890, says if ecgonin is treated with caustic soda or potassa, it changes into the isomeric isoecgonin. If the chloride of this base be suspended in alcohol, in which it is insoluble, and hydrochloric acid gas be passed into the mixture, it becomes clear. When evaporated to dryness, the residue taken up with water, the solution made alkaline and shaken with chloroform, beautiful prismatic plates of isoecgonin ethylether separate. Isococaine is obtained from this by heating with two parts of benzoylchloride for a short time in oil, both up to 150° or 160°. The melting point of isococaine is at 44° C., that of cocaine at 98°. With hydrochloric, nitric and hydrosulphuric acids, isococaine forms sparingly soluble salts. The process for making it has been patented by the firm Bohringer, in Mannheim. Its advantage over cocaine is a quicker production of anæsthesia. The oculist cannot use it, as it is even more of a local irritant than cocaine.

Cases of Prolonged Fasting.

Science, October 10, 1890, says a correspondent of the *Lancet* writes as follows: "The name of General Colletta, author of the *History of the King of Naples from 1734 to 1825* is one of the most respected in the annals of modern Italy, and his reputation for discernment and veracity may fairly be placed on a level with that of the Duke of Wellington in our own country. His description of the terrible earthquake which in 1783 devastated Calabria, and was severely felt throughout the Kingdom of the Two Sicilies, is of unquestioned authority, and from it the following incidents are extracted. They refer only to persons and animals imprisoned beneath the ruins caused by the earthquake. It is only necessary to add that the facts were ascertained by Gen. Colletta's personal investigations at the scene of the catastrophe. 1. A female child, eleven years of age, was extricated on the sixth day and lived; and another girl, sixteen years of age, Eloisa Basili, remained under ground for eleven days, holding in her arms an infant which had died on the fourth day, so that it was decomposed and putrefied at the time of her rescue. She was unable to free herself from the shocking burden in her arms, so closely were they hemmed it by the fallen wreckage. 2. More wonderful still, as regards duration of life, were certain cases that occurred among animals. Two she-mules existed under a heap of ruins, the one twenty-two days, the other twenty-three; a fowl lived for twenty-two days; and a pair of hogs, which were completely entombed, remained alive thirty-two days. The human beings who had undergone these unwonted privations, when interrogated as to their sensations, replied, 'I can recollect only up to a certain point, and then I fell asleep.' When it is remembered that all the creatures thus circum-

stanced were deprived entirely of water or other liquids, it is hardly to be wondered at, that, though there was no desire for solid food, they displayed on their liberation an insatiable thirst, and, the author adds, partial blindness—*sete inestinguibile e quasi cecità.*"

Resuscitation of the Apparently Drowned.

The *Medical Record*, Nov. 8, 1890, says: For the revival of persons who have been nearly drowned, two chief methods (with numerous slight modifications of each) are in use: the "Sylvester" and the "Marshall Hall." In 1862, a committee appointed by the Royal Medical and Chirurgical Society of London, to consider the rival claims of the two methods, reported in favor of the method of Sylvester, on the ground that the amount of air introduced into healthy lungs by this method was double that introduced by the method of Marshall Hall. The committee recommended that the body should be placed at an angle of thirty degrees, face downward, with the head lower than the feet, the mouth being open and the tongue drawn forward. The escape of fluids might be assisted by slight pressure on the back. After a few seconds the body should be laid back downward with a cushion under the shoulders, the tongue hanging out of the mouth. About fourteen times a minute the arms should be drawn above the head and then lowered and pressed, by the elbows, against the chest.

In the Transactions of the above-mentioned Society for 1889, Dr. Bowles criticises very earnestly the conclusions of the committee, which had been endorsed by the Society. The committee based its report upon experiments made with the *empty* lungs of animals. The physician, however, has to deal with human beings whose lungs are filled with fluid, mixed with air in a blood-stained froth. Under these conditions the most useful method must provide not only for the inspiration of air, but also for the escape of this frothy liquid from the deeper air passages. The sudden introduction of a large quantity of air by the Sylvester method is injurious, because at the same time the froth is drawn deeply into the finest tubes, which before contained a little air. By the Marshall Hall method, however, the air is introduced gently and in small quantities, and the froth is not drawn in more deeply, but is gradually expelled with each expiratory movement. Dr. Bowles supports his statements by the recital of a number of cases which he has treated.

After the patient has been placed for a moment with face downward to allow the escape of water from the mouth and throat, he is turned on the side and *kept on that side* continuously, except when (about fifteen times a minute) the body is rolled for a few seconds upon the face again. By *keeping the same side always up* the lung on that side becomes clear. Turning first one and then the other side up is dangerous, because thereby the partly cleared lung is suddenly flooded with fluid from the lung which was downward. It is better to clear one lung entirely than to have both half cleared. Each time the body is turned upon the face a little more froth and water escapes from the mouth and nostrils. If one lung is thus cleared it may escape the inflammation which results from the inspiration of water. When the upper lung has been almost cleared, Dr. Bowles finds it useful to raise the upper arm above the head as in the Sylvester method, since the entrance of larger quantities of air into the lung is now safe. Pressure on the back at each pronation assists the escape of water somewhat, and it has a good influence on the heart, aiding the propulsion of blood towards the lungs. The continued use of the prono-lateral method is an excellent mode of keeping the pharnyx clear of obstruction.

Eleventh International Medical Congress.

Dr. Guido Baccelli, President of the Accademia Medica of Rome, and Professor of Clinical Medicine at the Sapienza, presided at a recent meeting of the Società per il Bene Economico di Roma, to consider the means of ensuring the success of the next International Medical Congress to be held at Rome. Among the adjuncts to the Congress there will be an International Exposition of Hygiene. Florence, which has hitherto led in hygienic progress in Italy, has promised energetic co-operation, and Turin and Milan are expected to do likewise. Concurrently with the Medical Congress, it is expected that an International Exposition of the Industries of All Nations will be held. The early summer—May or the beginning of June—or the early autumn months—September or October—will probably be selected for the Medical Congress.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

EPIDEMIC HYSTERICAL ECSTASY.

An interesting account of an epidemic of hysterical religious ecstasy is reported by J. W. Hjelmann, in the *Finska Läkare Sällskap Handl.*, as quoted in the *Wiener Med. Presse*, June 15, 1890. The epidemic occurred in the northeastern part of Finland, and began at a dance, a girl sixteen years old being the first subject. During the course of the entertainment the patient was suddenly seized with violent convulsions. A few days later a second girl, who was taking the place of the first, was also seized with similar convulsions; and in a very short time twenty or thirty persons, mostly young women, were similarly affected. During the first part of the epidemic, the symptoms were merely those of convulsions, but later, after recovering from the convulsions, some of the patients began to preach, and the populace came from far and near to hear these—as they thought—inspired sermons. Many of the listeners had their initial convulsion during these meetings. The attacks were of a hysterical nature. In a few cases there was anæsthesia; but in the milder cases the convulsions were absent and were replaced by hysterical hiccough. In all there occurred about fifty cases, and the subjects included five men.

With the approach of winter the epidemic gradually died out, after having lasted for half a year. Hjelmann concludes by drawing attention to the fact that the province in which the epidemic existed, is almost shut off from intercourse with the outside world, and that the people's intellectual development is unusually low. A similar ecstatic religious movement had occurred in the province fifty years ago.

The study of epidemics of hysterical ecstasy takes one naturally back to the time of Mesmer, and his séances. His patients, seated around a tub of water supposed to be magnetized, would gradually become more and more excited until they were seized with violent convulsions and were conveyed to padded rooms; there to "fight it out" with their supposed or real disease. The condition thus produced was undoubtedly one of hysterical ecstasy. Similar séances were held in various parts of France, largely attended and fruitful of the same hysterical exhibitions.

In Arabia, among the Mohammedans, and in India, among the Fakirs, religious festivals are attended by similar epidemics even at the present day. An eye-witness describes such a scene as follows: It occurred at a religious festival of the Mohammedans. A "son of the Prophet" was present, in his huge green turban, and had promised to heal the sick and perform other miracles. The descendant of Mahomed sat on a canopied dais at one end of the enclosure, and in a circle around him, squatted a large number of men with

tom-toms and horns. Presently a weird chant was started, accompanied by beating of the tom-toms, which gradually increased in volume and energy, the "believers" evidently growing more and more excited. Presently a man, bared to the waist, stepped into the centre of the enclosure; lifted above his head, by point and hilt, a sword with an edge as keen as a razor's, and, crying: "There is no god but Allah, and Mahomed is His Prophet!" brought the sword violently down against his abdomen, and then fell flat on his back. The son of the Prophet then stepped from the dais and, steadied by two servants, stood upon the blade, over the man's abdomen, muttering some prayers in the meanwhile. He then returned to the dais, and the man lifted the blade from his abdomen. There was no cut!

This clever trick had a marvelous effect upon the chanting crowd. Several sprang up, and seizing axes or knives, proceeded to mutilate themselves in the most horrible manner. Others leaped, shouted and finally fell in violent convulsions, frothing at the mouth and struggling violently. The performance continued for several hours. At its close the mutilated men were carried to the Prophet, who touched their wounds and offered a prayer. No "healing" was visible. Those in convulsions and others unconscious were also carried away. These festivals last for days, often weeks, and their effects still longer.

Coming to our own country, we see similar hysterical manifestations, although of much milder type, occurring during religious revivals. While, happily, these do not become epidemic, yet cases of hysterical ecstasy, taking the shape of trances or convulsions, are frequently the outcome of emotional religious movements.

A study of hysterical ecstasy shows that it is a pathological condition, and if encouraged to any degree would result in serious injury to the subjects of it. The arousing of such conditions, whether at revivals or mesmeric séances, should therefore be vigorously discountenanced by the profession.

SUGAR IN PATHOLOGICAL EFFUSIONS.

Our knowledge of the composition of ascitic, pleuritic and other pathological effusions has been very imperfect hitherto, especially with regard to the presence in them of sugar. The investigations of Dr. William B. Ransom, therefore, which are published in the *Practioner*, October, 1890, are very welcome and deserve brief notice, even though Dr. Ransom modestly admits that his conclusions to some extent are tentative. Before examining for sugar, he removes the proteides in transudates and exudates, by boiling the fluid after faintly acidulating it with acetic acid. If this does not suffice, the fluid is evaporated to dryness on a water-bath and the residue is extracted with boiling alcohol. The tests used for sugar were the well-known ones of Fehling, of fermentation with yeast and picrate of potassium, Moore's test with liquor potassæ, and the reduction test with bismuth. For quantitative examination, the filtrate, obtained as described, was tested with Fehling's solution, the sugar being reckoned as dextrose.

Only a brief summary of Dr. Ransom's conclusions will be given. Ascitic fluids, he says, probably always contain sugar, usually not less than one-tenth of one per cent. When the ascites is due to portal obstruction the amount is greater, the average of nine cases being fifteen-hundredths of one per cent., and this increases when sugar is given as food. This fact indicates that sugar normally is absorbed by the portal vein and not by the lacteals. The fluid of ovarian cysts contains no sugar, or only a trace of it. Œdema fluids, on the contrary, contain sugar, but not more than one-tenth of one per cent. Inflammatory serous effusions, as in blisters and pleurisy, contain sugar in less amount and less constantly than do transudates, the sugar probably being absorbed by the out-wandering leucocytes. Pus contains

no sugar. Hydrocele fluid, when free from degenerative products, contains sugar. Cerebro-spinal fluid may, under certain conditions, contain sugar, but Dr. Ransom says this is not the most constant reducing body. True sugar may also be present in hydatid fluid.

Dr. Ransom's investigations are, of course, interesting from a physiological point of view, as showing how widely distributed sugar is in the economy; but they have also a direct clinical bearing. For example, a larger percentage of sugar is to be expected in pleural and pericardial effusions than in hydro-pericardium and hydro-thorax; indeed, the presence of sugar in any amount would appear to indicate the latter rather than the former. Again, the finding of sugar in a doubtful case, suspected of being one of ovarian cyst, would make the existence of the latter disease doubtful.

We do not desire to exaggerate the importance of Dr. Ransom's results, but we think them interesting and as such deserving of notice; and we have pointed out the way in which they can be made clinically useful.

NEW WAY OF ABUSING MEDICAL CHARITY.

We fear somebody has been playing a trick on the New York *Medical Record*, which, in its issue of November 8, says:

"The celebrated surgeon, Professor Billroth, of Vienna, was asked to perform an operation upon a Russian Jew, and he agreed to do it for a fee of two hundred and fifty guineas. On making the journey to the small town in which his patient lived, he was informed that the Jew had suddenly died. However, in order that he should not suffer loss by the transaction, the Professor was asked whether he would treat five hospital patients for a fee of fifty guineas each. He accepted the offer, and did the work; and just as he was starting homeward he ascertained that one of the five patients upon whom he had operated was the Jew who was reported to have died."

This seems to be so obvious a paraphrase of a joke, published long ago in the *Fliegende Blätter* that it is impossible to avoid the conclusion that either the editor of the *Record* or Professor Billroth is not a constant reader of that admirable and entertaining journal.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

LATIN GRAMMAR OF PHARMACY AND MEDICINE. By D. H. Robinson, Ph. D., Professor of Latin Language and Literature, University of Kansas, with an introduction by L. E. Sayre, Ph. G., Professor of Pharmacy in, and Dean of, Department of Pharmacy, University of Kansas. Philadelphia: P. Blakiston, Son & Co., 1890. Price, $2.00.

This is a most admirable book, one which ought to be in the hands of everybody who wishes to write medical articles, and to have his prescriptions correct. It contains a great deal that nobody will care for outside of schools and colleges; but it also contains a great deal which would be invaluable to medical writers, and especially to medical editors. If the former class would devote themselves with sufficient zest to a study of this book, it would no doubt add materially to the longevity of the latter. It might not be improper, perhaps, to say that this book might be especially commended to the careful attention of writers of works on materia medica and therapeutics, as it has been some time since we have seen a work on this subject which did not contain errors such as this book is calculated to prevent.

TRANSACTIONS OF THE SOUTH CAROLINA MEDICAL ASSOCIATION. Fortieth Annual Session, at Laurens, S. C., April 23 and 24, 1890. 8vo, pp. x, 130. Charleston, S. C.: Walter, Evans & Cogswell Co., 1890.

The volume opens with the annual address of the President, Dr. James Evans, of Darlington. Dr. James G. Gilder, of Newberry, reports a case, probably of Cyst of the Spleen; Dr. T J. McKie, of Woodlawn, inquires into the causes of Pulmonary Tuberculosis in the Negro; and Dr. Cornelius Kollock, of Cheraw, reports a Laparotomy for Uterine Fibroids. Dr. Charles W. Kollock's paper on Young Eyes, is an interesting one. He urges great watchfulness on the part of the family doctor, and details the treatment of the common eye affections of children He also has a paper on Some Cataract Cases Dr. R. B. Rhett, Jr., reports a case in which an Intraligamentary Cyst was successfully treated by Iodine injections, and also one on Cholecystotomy in a Pregnant Woman Dr. R. A. Kinlock gives the details of some Laparotomies for Removal of the Uterine Appendages; Dr. O. B. Mayer, Jr., reports Two Cases of Retention of the Menses. The Report on Ophthalmology is by Dr. George Howe; that on Practice, by Dr. T. P Bailey. Dr Manning Simons, of Charleston, reports an interesting case of Aneurism and Arterio-venous Aneurism of the Femoral Artery and Vein; Dr. Thomas Legare,

of Charleston, has some Remarks on the Treatment of Pelvic Peritonitis. The Report on Surgery is by Dr. O. B Mayer, Jr.; that on Obstetrics by Dr. P. G De Saussure. Dr. E. F. Darby has a timely paper on Physical Culture.

We notice that the minutes of the meeting have been omitted from the volume; whether by accident or design does not appear. The character of the papers read shows that the Association is capable of very good work.

CORRESPONDENCE.

Consumption Among Firemen.

To the Editor.

Sir: Permit me to call renewed attention to some statements made by Dr. Mays in the Reporter of September 27, in an article on "Consumption among Firemen." Dr. Mays evidently was misinformed, or labored under a serious misapprehension of alleged facts. He states that the percentage death-rate of consumption in firemen is very high, notwithstanding that the previous health of the members of the fire departments in the respective cities from which he gained his facts was good, and notwithstanding the fact that the members are selected from a healthy class of men, that they are not exposed to any infection, and that they lead an out-door life. Hence as their circumstances are antagonistic to bacillary invasion, the excessive mortality must be due to causes other than specific infection.

I have not had either the time or inclination to inquire into the specific details of fire departments in the many cities mentioned by the author, but opportunity was afforded for inquiry into the fire department of this city, and as the facts gathered are in direct variance to those of the author referred to and contradict all his premises, his conclusions regarding all the departments are vitiated. I am indebted to the efficient clerk of the Philadelphia Fire Department for my data.

1. Are the men who now, or did, compose the Fire Department during the period of the writer's statistics (1871–1890), selected? That is, free from the hereditary taint, past or present lung disease, and not exposed to infection a short time before appointment?

Before the advent of the present government of this city, four years ago, physical examination of applicants for firemen was not held, except during two years of the term of Mayor Smith, just preceding the present term. It was notorious that men infected with consumption, with strong political influence, were placed in the Department to secure the death benefit that falls to deceased members.

Mr. Watson, who has been in the Department since its organization, informs me that 13 of the 33 who died of consumption had it before entering, and I find from the table he has given me that 5 died within two years of the time of admission, one as soon as seven months. It is interesting to note that of the actually selected men thus admitted during the past eight years, not one died of consumption. If the 13 cases are eliminated as per the above, it is seen that the deduction of more than one-third — nearly one-half—must be made from the author's percentage calculation.

2. Is the occupation of the fireman properly an out-door one?

To presume such to be the case, one must believe the city in a constant state of conflagration. The most superficial observer knows of the lazy life the fireman leads, of the fattening process he undergoes, and how in winter he whiles away hours in the rooms of the engine-house, smoking, and leading a truly enervating life.

3. Are the firemen isolated? Do they come in contact with tubercle bacilli or the expectoration of consumptives?

By the above, or the death-record of the departments, it is seen that each fire-house may have one infected person in it. Moreover, the rules of the Fire Department of Philadelphia allow a man one hour three times daily to go home, and twenty-four hours each week to spend with his family, or where he will. Is this isolation?

To prove the men who died of consumption were not infected by the tubercle bacilli, one must prove their freedom from the possibility of contamination during each hour of absence from the department.

We hold, therefore, that it is not proven that firemen are a healthy selected class of men, that their occupation is an out-door one, that they are not confined to sunless and poorly-ventilated dwellings, or that they do not come in contact with tubercle bacillus or the expectoration of consumptives, "except by chance," or finally, that consumption is the cause of one-third of their deaths.

It is to be regretted that the methods adopted by the author to prove the propositions laid down were not given with the

same mathematical precision that we know obtains in the proof for the relationship of the tubercle bacillus to tuberculosis. Any one familiar with the close reasoning and absolute step-by-step demonstration of the statements of Koch, none of which have thus far been refuted, cannot but be impatient with the lax processes that are employed to repudiate his statements. Did I not fear that I was trespassing on your valuable space it would give me great pleasure to call attention to some facts which would refute the arguments of the authorities which the learned gentleman quoted in the article just referred to, as well as some misapprehensions which he appears to be laboring under, both as to the etiology of tuberculosis and its relation to pulmonary phthisis, as well as the assertions of authorities which he quotes. I am constantly reminded, however, of the fact that so little time is given us to build up the science of medicine and add new facts, that it is scarce worth while to waste it in counteracting those who are anxious to pull down.

Yours truly,

J. H. Musser, M. D.

Philadelphia.

Olive-Oil for Gall-Stones.

To the Editor.

Sir: I see in the Reporter, September 20, 1890, page 353, the report of a paper read by Dr. Burbank, denying the value of olive-oil in the treatment of gall-stones, also, the statement that what was expelled was not gall-stones, etc. This is a bold position for a doctor in the cotton-seed oil country, to take. I have used olive-oil in cases of gall-stones for some years, and can tell a gall-stone from dark-green masses, etc. I have patients who come for treatment with all the symptoms usual in those cases, and in every case the olive-oil treatment is a success. I use the pure virgin oil, and import it myself, and in every case I examine the stone carefully; therefore I am sure of what I speak. I, of course, use other medicines in those cases, as the general conditions of the constitution requires. I am now treating cases, and during the last few years have treated a large number, that had been under hypodermic injections of morphia and cocaine to allay the pain. In most of these cases I use a pill, at meals, of corrosive sublimate and iodide of potash for a few days, at the same time using the oil. My own experience proves its sure results.

Yours truly,

C. R. Earley, M. D.

Ridgway, Pa.

Notes and Comments.

Local Bleeding for Congestion of the Lungs.

In *The Lancet*, November 1, 1890, Dr. J. C. Simpson reports and recommends a bold method of blood-letting directly from the substance of the lungs. He describes a case in which he did this by accident, and then other cases in which he did it deliberately. In the first the patient was a woman with Bright's disease, which was not improving under dietetic and other treatment. One day she was becoming comatose, with fibrillary muscular twitchings, and intense dyspnœa, accompanied with œdema and congestion of the lungs. Under these circumstances venesection was indicated, as the ordinary treatment for such a condition failed to relieve it. In order to render the pulmonary phlebotomy as safe as possible, the aspirator was used, and the largest canula thrust into the lung substance at the level of the ninth costal interspace on the left side, the absence of pleural effusion having been previously ascertained. No blood flowed, and after various manipulations, reducing and increasing the suction power, Dr. Simpson removed the whole of the aspirating apparatus, and very shortly after there was a free flow of blood from the canula, which had been left *in situ*. After the withdrawal of twelve ounces of blood the canula was held *in situ* with the finger over the end to allow of a clot forming, and then it was slowly withdrawn altogether. A piece of plaster was applied over the puncture, but a flannel bandage could not subsequently be retained in position. The patient was immediately and markedly relieved, both as regards the cerebral and pulmonary conditions. No effusion took place, there was only trifling hemoptysis and a suspicion of a small patch of pleurisy, without a rise of temperature. The patient remained in a greatly improved condition for a considerable time after this, though she ultimately died comatose.

A third case similarly treated was one of almost complete breakdown of compensa-

tion in cardiac disease, there being double mitral and aortic systolic murmurs as well as well-marked dilatation.

A fourth case was one which also terminated fatally, death being due to uremic convulsions. In this case, instead of a flow of blood, the œdema was so pure that only serous fluid escaped very slowly, and coagulated quickly, thus rendering the process futile. In spite of brachial venesection, which was immediately performed on account of the urgent symptoms, this patient died of the convulsions.

These are four cases in which this procedure has been carried out—intentionally and systematically in the last three. So far as Dr. Simpson is aware, deliberate puncture of the lung in such cases with the intention of depletion has not been before practiced, and it is on this account that he desired to record his cases. By some it may be said to be unjustifiable or too heroic treatment; but with this he does not agree, provided that suitable cases are chosen, and that the operator is familiar with the use and abuse of the exploring needle: in other words, that he has the manipulative skill requisite for such an operation. These cases were all of a hopeless character, and only palliation at best could be expected, except in the cardiac case, the third recorded, and in it Dr. Simpson regretted that time had been lost in ordinary medical treatment. Dr. Simpson says, Whether his method would be useful as a *dernier ressort* in cases of acute uremia with pulmonary symptoms remains to be seen; but there was certainly immediate improvement in the cases where blood was abstracted. The aim and object is to try to get the good of venesection without such a loss of blood and its subsequent retardation of convalescence. The process is analogous to a pulmonary apoplexy, which is recognized as being of the utmost benefit in certain cardiac cases, and the pulmonary lesions in both cases have a strong similarity. The broad indications for this seem to Dr. Simpson to be that the case is one which has extreme pulmonary congestion and œdema; absence of effusion into the pleural cavity; general venous stasis and cyanosis, all of which may occur in the progress of certain heart and kidney affections; and that other treatment, medicinal and mechanical, has failed to relieve the symptoms. The co-existence of such congestion without pleural effusion is somewhat rare, and therefore this limits the practice; for the mere aspiration of the pleural effusion is almost invariably followed by such relief in cardiac cases that venesection is not required. It is therefore a necessary preliminary procedure to negative the presence of effusion in any quantity that would embarrass the heart's action and impede the pulmonary circulation. To do this thoroughly an exploring needle must be used. The condition of the lungs in a suitable case is such that, as regards the danger of subsequent pneumothorax, little or no air is being interchanged at the proposed seat of puncture, and the elasticity of the lung is quite sufficient to prevent any serious oozing taking place.

In practicing this method Dr. Simpson says the right side should be chosen if both sides are equally free of effusion, or are generally engorged. The site of puncture should be not higher than the ninth interspace posteriorly. The needle to be used is the largest usually supplied with an aspirator, the parts used being the canula and the corresponding trocar and fittings, but it will be found advantageous in some cases to use a probe of a size smaller than the canula.

The puncture should be made in one thrust, so that there be no danger of one or more small punctures of the lung. If this be not done the patient will cough and be troublesome, as the visceral layer of pleura is very sensitive, but with one thrust there is little or no discomfort. The depth of canula introduced need not be great at first, and it could only be by great carelessness that any vessel of any size could be injured. The *tactus eruditus* will at once advise the operator of the fact that the end of the canula is not in a free space containing fluid. The canula being steadied and the needle withdrawn, the operator should wait for a few seconds to see if any blood flows. If not, the canula should be moved, so as to produce slight laceration, then slightly withdrawn and usually there is a free flow. If clotting takes place, the smaller probe should be introduced and the canula cleared. The probe being smaller, allows of blood to flow, although it may be *in situ*, and keeps any lung tissue from the end of the canula.

The amount of blood to be abstracted varies according to the case and the results produced, it being as a rule less than would be required were venesection adopted. The extraction requires some care. The finger should be placed on the angular aperture

of the canula and either the needle or probe introduced along the canula and kept there for a few minutes, to allow of clotting to take place in the lung, and then slowly withdrawn.

The local after-treatment consists in applying a piece of plaster to the puncture, and a bandage if the dyspnœa will admit of it.

The Beef Tea Delusion.

Dr. E. B. Ward, says, in the *American Lancet*, Nov., 1890:

There are certain fallacies in the practice of medicine which any one can see through, but which have been handed down from one generation of doctors to another, until they came to be accepted and even taught as truths. Perhaps there is not one of them more generally adopted, or more harmful, than the beef tea delusion, and this was just now brought to my mind by reading, in a late medical magazine, "Prof. Keen's Method of Making Beef Tea." His method is much the same as was taught me thirty-five years ago, and which, even then, my juvenile medical mind revolted against to such an extent that I have not given beef tea for over thirty years. I substituted milk, which even so recently as that was thought by good authority to be a dangerous pabulum in low stages of fever. My cases of death, however, were fully as rare, and it seemed to me more rare, than with patients otherwise managed. Here is Prof. Keen's method: Select round or rump, as it is useless to spend money for choicer beefs when this is just as good for the purpose. Take one pound, chop it into fine pieces about the size of the end of the little finger, and soak in one pint of cold water for two hours. Then boil the whole, strain, and add enough water to make a pint. Add sufficient quantity of salt, pepper, etc., to suit the taste. The object of soaking in cold water is to get the essence out of the beef. If warm water is used, a coating of albumin coagulates on the surface of the beef, thus preventing the essence from escaping.

Now let us try to make some of this beef tea.

We take a pound of finely-cut beef and pour a pint of cold water on it, and let it stand two hours—while we write about it. The water is not near sufficient to cover the beef, but with occasional agitation we get at the essence. At the end of two hours we find the meat surrounded by a reddish-colored liquid. Put a little of this fluid into a test-tube, and hold it in the flame of a spirit lamp. You see it coagulates to the extent of one-fourth, perhaps. What is that? Well, never mind now, we are going to make some beef tea. Now, we proceed to "boil the whole." He doesn't say how long, and it does not make much difference so long as the water holds out. Now "strain and add sufficient water to make a pint." You perceive that it is too strong and has to be diluted. Let us take a little of this concentrated essence in a test-tube and examine it. Here is a translucent fluid with a bland taste, a neutral reaction, and a slight odor of beef. By closer inspection you observe little fine particles of sediment slowly settling. This, Pavy says, should be stirred up and given with the tea, but as it is only particles of coagula which have skipped through the strainer let us have it out. If part of it ought to come out, it all should. So we will filter this liquid, and you observe we have a limpid almost colorless fluid left, and a slight deposit on the filter. What is it? Well, we shall see shortly. Now take a little of this liquid in a test-tube and drop a few drops of nitric acid into it. There is no precipitate formed, so we know there is no albumin or fibrin in it. What is in it? Well, there is a little saline matter, and—a world of disappointment to any one who tries to sustain life with it. That is about all. Why!—Well, the thing is too absurd to talk about. Common well-water containing the average quantity of bacteria is more nourishing.

Thousands of sick people have been starved to death on this diet, and I want to enter my solemn protest against it before it is everlastingly too late. What you want is the albumin and fibrin of the meat in a condition requiring little digestive power, and that will be readily assimilated. The moment you coagulate these ingredients by heat you render them practically indigestible. These, however, by this process are mostly strained out and the fluid is left inert, or nearly so.

Good milk is preferable always, but if you must give beef tea, *never boil it.* Liebig says 120° F. is the highest temperature to which it should be subjected. It is not very inviting in its general aspect, but it holds in solution the ingredients that you want, and which are rendered useless for a weak diges-

tion by boiling. Liebig's plan is to add a little hydrochloric acid.

Perhaps there is nothing in the whole round of dietetics, however, that holds so much real needed food, in a given space, as good rich milk punch—teetotalers to the contrary notwithstanding.

Koch's Cure for Consumption.

The *Medical Record*, Nov. 15, 1890, says, editorially: As we write, the daily papers are printing, with every issue, some fresh news of the wonderful, and as yet secret, "cure" for consumption discovered by Dr. Robert Koch. The interest in it is natural and intense. In this country there are some two hundred thousand sufferers from this fell disease, and in Europe and other parts of the world a still greater army of victims are hopefully looking for some cure, or patiently awaiting the end.

The expectations aroused by the numerous and mysterious reports that are issued from Berlin must be very great. It is well, therefore, to consider how much can be in fact realized by the announced "cure." Of it we know at least this, that it is a germicide, and that its action depends upon its destroying the vitality or power of growth of the tubercle bacilli. If this is the case, it is a remedy that must have various limitations to its usefulness. Phthisis is, in most cases, in its inception an infectious bacillary disease. But after lung tissue is once well invaded, and necrotic and inflammatory processes set in, the infection is a mixed one, and pyogenic organisms are largely in control. No agent which simply destroys tubercle bacilli can, therefore, seriously modify the phthisical process. Germicides cannot cure phthisis in its second and third stages.

We are confident that Dr. Koch will not claim this for his "cure." Already it is stated that cases of lupus, of tubercular joints, and of phthisis in the first stage have been cured. But all these forms of tuberculosis can already be relieved by surgical and hygenic measures at our disposal. It remains to be seen, therefore, whether Koch has really supplied us anything which will carry the treatment of tuberculosis any further than it already has been brought.

One thing further, perhaps, he has achieved, viz., a method of prevention for those susceptible or exposed to the disease. This may be a gain, although the prevention of phthisis in individual cases is almost always possible if proper care is taken.

Orton Prize.

Dr. J. G. Orton, ex-President of the New York State Medical Association, has offered a prize of $100 for the best short popular essay on some subject connected with practical sanitation, under the following conditions:

1. Competition to be open to all.

2. Essays to be forwarded to the Secretary of the Association, Dr. E. D. Ferguson, Troy, N. Y., not later than August 1, 1891, accompanied by the name of the author under separate seal.

3. Examination and award to be made by a Committee appointed by the Council of the Association.

4. The successful essay to be read at the next annual meeting of the Association, and, if approved by the Council, to be offered for publication in the secular press, and issued in tract form or otherwise for general circulation.

5. Authors of essays, unsuccessful as far as the prize is concerned, but found worthy of special commendation, to receive intimation as to a proper disposition to be made of them.

Leprosy in Louisiana.

The *New Orleans Medical and Surgical Journal*, November, 1890, says:

In olden times a leper was set down as a source of danger to a community, and he was placed in an institution where he could drag out his weary existence without endangering the health of other people. Sometimes this quarantine amounted to banishment and was attended with sad hardships; but it was effectual, and leprosy almost became extinct. In countries where the disease was not regarded as communicable, it was not blotted out. In Norway leprosy is not regarded with special horror or fear, and the disease is allowed to linger there. In Louisiana we seem to be as brave or as foolishly indifferent as the Norwegians. There are no statistics from former years which would enable us to say whether the vile disease is increasing or diminishing; but there can be no doubt that the presence of more than fifty lepers in a State containing 1,140,600 inhabitants is sufficient to justify

the expenditure of enough money to make them no longer a source of danger. Not many months ago a single leper was found in London. He was a butcher, and the discovery that a leper had been handling the mainstay of British life and the British constitution—namely, the beefsteak—almost threw the world's metropolis into a panic. The news was telegraphed to all parts of the English-speaking world. Meetings were held under the auspices of the Prince of Wales, whence the patient was dubbed "the Prince of Wales' leper." Some one advocated the founding of a leper hospital, but nothing was done, although, we believe, subscriptions were raised. In time the scare died out.

After commenting on the undue prominence given to the case, the Editor contrasts it with the indifference to leprosy in New Orleans. He says that while attending a play at the most popular theatre in New Orleans, on October 19, 1890, he saw a youth pass by him between the acts who presented the typical leonine expression of tubercular leprosy. The theatre was crowded; it was a Sunday-night performance, always the best patronized in our wicked city. The leper was well dressed; he passed in and out among the throng like any one else. About two years ago the writer went, one afternoon, into a well-known restaurant to get a lunch. Just as he was about to begin operations three men entered and sat at a table not more than five yards distant. The husky voice of one of the men attracted the writer's attention. A careful examination showed that the man was suffering from leprosy in an advanced stage; his face had the leonine expression, and the husky voice doubtless indicated that the disease had invaded the larynx. A waiter was called and asked if the man with the hoarse voice was a regular patron of the eating-saloon. The reply was in the negative. The writer then ate his lunch. About two months ago he, while walking along the river front, saw a group of women and girls standing in a doorway and talking. When he was abreast of the group he was struck by the husky voice and labored speech of an old woman. True to his medical instincts, he turned his gaze upon the sufferer and saw a well-marked case of leprosy. He was walking along not very slowly, but he noticed a small stand or show-case containing bread and cakes for sale. The old woman was bare-headed, and from appearances seemed to be an inmate of the house in which the cakes were sold.

After making these statements the Editor adds: "Now, is this right? These incidents are not much, but they indicate a horrible degree of neglect on somebody's part. One leper 3,000 miles away can furnish our papers with palatable news, but fifty lepers at home are allowed to pass unnoticed. Unfortunately, frequent contact with our own lepers has made us callous and indifferent to the risk we are constantly exposed."

He says that it is the opinion of a large majority of the men who are familiar with the disease that the best known means of preventing its spread is by segregation under State or government authority, and that a member of the staff of the *New Orleans Medical and Surgical Journal*, who has, perhaps, seen more cases of leprosy in America than any other American, has advocated this plan before the medical public as well as before individual members of the State Legislature.

Lycoming County Society Lectures.

The Lycoming County Medical Society is giving a course of lectures by prominent physicians this winter. Dr. John B. Roberts, of Philadelphia, opened the course October 6, with a paper "On Simplicity in Fracture Dressings;" and Dr. J. C. Wilson, of Philadelphia, lectured November 4, on "The Treatment of Enteric Fever." Both lectures were attended by a large number of physicians of the West Branch Valley, the representation extending from Sunbury to Renovo. Other lectures will follow monthly.

Mütter Lectures of the College of Physicians of Philadelphia.

The course of lectures on Surgical Pathology, provided in accordance with the will of the late Prof. Thomas D. Mütter, will be delivered during 1890–91 by Prof. Roswell Park, of Buffalo, New York. The first series of five lectures will be given in the hall of the College of Physicians, corner of Thirteenth and Locust streets, on December 4, 5, 6, 8 and 9 at 8.15 P. M.

The subjects are as follows:

1. Introductory. Study of the blood and of some phases of the inflammatory process. Thrombosis. Embolism. Hemoglobin and

Oligochromemia. Ptomaines. Conditions predisposing to infection.

2. A study of pus and of pyogenic organisms, obligative and facultative.

3. Surgical sepsis and the organisms which produce it. Resumé of experimental work. Surgical fever, Intestinal Toxemia, Sapremia, Septicema and Pyemia.

4. Peritonitis: forms and causes. Testing the relative values of antiseptics.

5. Tetany and Tetanus.

The members of the medical profession are cordially invited to be present.

Pasteur Institute Statistics.

During the month of September, one hundred and forty-one persons were treated in the Pasteur Institute at Paris. Of this number, twenty-four were bitten by animals supposed to be rabid, from the success of "experimental inoculations;" ninety were bitten by animals considered rabid by veterinarians; twenty-seven were bitten by animals "suspected" to be rabid. The animals that did the biting were: dogs, one hundred and twenty-three times; cats, sixteen times; asses, twice.

NEWS.

—Dr. B. J. Weyll, a well-known citizen of Camden, died on Saturday, in his eighty-sixth year.

—Dr. R. Curtis Gray has removed to 345 Lafayette Avenue, Brooklyn, N. Y. Telephone call, "Bedford, 593."

—Miss Annie A. Hintze, head nurse at the Pennsylvania Hospital, has resigned, to accept a position in the American Hospital, at Rome.

—An epidemic of diphtheria was recently prevailing at Garner, Iowa, and all the schools there were closed. Deaths from the disease occurred daily.

—A wealthy citizen of Wilkesbarre, Pa., had not, it was said on November 24, eaten a morsel of food for two weeks. He persistently refuses to eat, insisting that he is dead and does not require food.

—Dr. Robert H. Bolling will take Dr. Cleveland's place as Senior Resident Physician at the Germantown Hospital, commencing December 1, and Dr. W. G. B. Harland will act as his assistant.

—The newspapers of November 21 reported that a physician in a suit for damages in a large city in the United States used the word "clonic," and four doctors called by the defence testified that there was no such word, either in the English language or as a medical term.

—Dr. J. H. McKellup, who was authorized by Governor Ross to thoroughly investigate the reported existence of glanders in Texas, has forwarded his report to the Governor. It states that the only section where glanders was found to have existed was in Dewitt county, where thirteen cases occurred among horses. All the affected animals have been killed.

—The Trustees and Medical Board of the German Hospital decided on November 20, that Dr. Carl Frese, Chief Resident Physician of the institution, should sail for Berlin to investigate Dr. Koch's recent discovery in the treatment of tuberculosis. Professor Ernest Laplace, of the Medico-Chirurgical Hospital, sailed November 20, on a similar errand.

—Dr. George T. Dare, for forty-eight years a practicing physician in Lancaster and Chester counties, Pa., met with a tragic fate at San Diego, Cal., a few days ago. He fell from a porch at the home of his son, David D. Dare, and one of his thigh bones was fractured. Being eighty-four years old the doctor's debilitated system was unable to withstand the shock, and death followed.

—A bazaar in aid of the Polyclinic Hospital, Lombard Street, above Eighteenth, will be given on December 3 and 4, under the auspices of the Ladies' Aid Society. The management has decided to make no charge for admission, trusting that those who attend will voluntarily contribute or make purchases. The bazaar will be made the occasion of affording opportunity to inspect the new hospital building, in which it is to be held.

—John Feeney created an uproar in a Chicago Court November 20, by smashing a rotten egg on the head of Dr. Kiernan, former physician in charge of the Cook county insane asylum. Feeney's sanity was being tried, and Dr. Kiernan was on the witness stand when the egg was thrown. Feeney then quietly turned over to an officer of the Court another egg, which he had in reserve in case the first one had missed its mark. The jury found Feeney insane.

CH. MARCHAND'S

PEROXIDE OF HYDROGEN

(MEDICINAL) H_2O_2 (Absolutely Harmless.)

Is rapidly growing in favor with the medical profession. It is the most powerful antiseptic known, almost tasteless, and odorless. Can be taken internally or applied externally with perfect safety. Its curative properties are positive, and its strength and purity can always be relied upon. This remedy is not a Nostrum.

A REMEDY FOR DIPHTHERIA; CROUP; SORE THROAT, AND ALL INFLAMMATORY DISEASES OF THE THROAT.

OPINION OF THE PROFESSION.

Dr. E. R. Squibb, of Brooklyn, writes as follows in an article headed "On the Medical Uses of Hydrogen Peroxide (*Gaillard's Medical Journal*, March, 1889, p. 267), read before the Kings County Medical Association, February 5, 1889:

"Throughout the discussion upon diphtheria very little has been said of the use of the Peroxide of Hydrogen, or hydrogen dioxide; yet it is perhaps the most powerful of all disinfectants and antiseptics, acting both chemically and mechanically upon all excretions and secretions, so as to thoroughly change their character and reactions instantly. The few physicians who have used it in such diseases as diphtheria, scarlatina, small-pox, and upon all diseased surfaces, whether of skin or mucous membrane, have uniformly spoken well of it so far as this writer knows, and perhaps the reason why it is not more used is that it is so little known and its nature and action so little understood. . . . Now, if diphtheria be at first a local disease, and be auto-infectious; that is, if it be propagated to the general organism by a contagious virus located about the tonsils, and if this virus be, as it really is, an albuminoid substance, it may and will be destroyed by this agent upon a sufficient and a sufficiently repeated contact. . . . A child's nostrils, pharynx and mouth may be flooded every two or three hours, or oftener, from a proper spray apparatus with a two volume solution without force, and with very little discomfort; and any solution which finds its way into the larynx or stomach is beneficial rather than harmful, and thus the effect of corrosive sublimate is obtained without its risks or dangers. . . ."

Further on Dr. Squibb mentions that CHARLES MARCHAND is one of the oldest and best makers of Peroxide of Hydrogen, and one who supplies it to all parts of the country.

CAUTION.—By specifying in your prescriptions "Ch. Marchand's Peroxide of Hydrogen (Medicinal)," which is sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing my label and signature, you will never be imposed upon. Never sold in bulk.

PREPARED ONLY BY

Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

A book containing full explanations concerning the therapeutical applications of both CH. MARCHAND'S PEROXIDE OF HYDROGEN (Medicinal) and GLYCOZONE, with opinions of the profession, will be mailed to physicians free of charge on application. ☞ Mention this publication.

BURN BRAE

A PRIVATE HOSPITAL

--FOR--

MENTAL and NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

EXTENSIVE AND BEAUTIFUL GROUNDS, affording perfect privacy and pleasing variety. House and surroundings unusually attractive and cheerful. Heat, light and ventilation perfect.

A PLEASANT, SAFE AND HEALTHFUL HOME,

With constant professional supervision. Music, games, open-air amusements, boating, etc., are provided for patients.

THE OLDEST INSTITUTION OF THE KIND IN THE UNITED STATES.

Both sexes received. A limited number of opium habitues admitted. Pleasant companions for female patients.

LOCATED A FEW MILES WEST OF PHILADELPHIA,

At Primos Station, on the Philadelphia and Media Railroad, from Broad Street Station, Philadelphia, Pa.

Clinical Lecture.

OPIUM.

BY H. C. WOOD, M. D.,

PROFESSOR OF THERAPEUTICS, UNIVERSITY OF PENNSYLVANIA.

I propose to take up to-day the subject of analgesics, remedies used for the relief of pain. Of these *facile princeps* is opium: the inspissated juice of the unripe capsules of the *Papaver somniferum*, or poppy. It is a very complex body, containing the alkaloids morphine, codeine, narceine, narcotine, etc., also meconic, thebolactic and sulphuric acids, extractives, a volatile odorous principle, and other substances of no importance. Of these various elements in opium, morphine and codeine are the only ones used in practical medicine. Narcotine is of interest, as to it is usually ascribed the depressing and sickening influences of the drug. Hence its elimination from all other preparations is an advantage.

In the study of the preparations to be used, we find that there are only a few worthy of consideration. The dose of the solid opium is one grain. The extract—twice the strength of the solid opium—is a preferable preparation, as it has lost the alkaloid narcotine, which has been removed by ether. Laudanum, containing ten per cent. of opium, is given ordinarily in the doses of fifteen minims—about twenty-five drops—each drop varying from one-half to two-thirds of a minim, according to the size and shape of the vessel used as a dropper. The deodorized tincture of opium contains no narcotine or oleaginous principle. It is always to be selected when a strong internal form of the drug is wanted. It is prepared by infusion, being a watery preparation, containing only enough alcohol to keep the drug properly. It is less liable to sicken than any other form of the drug. Its drop is nearly a minim in size. Tinctura opii, acamphorata, or paregoric, has in every fluid ounce two grains of opium, besides camphor and oil of anise, which give it its characteristic taste. It is more constipating than other preparations of opium on account of the camphor, and hence is more suited to diarrhœa mixtures. Eighteen drops of paregoric are equal to one of the deodorized tincture. The only other preparation of opium worthy of our consideration is the so-called Dover's powders—pulvis opii et ipecacuanhæ. They are now made of eight grains of sugar of milk to one grain each of ipecac and opium. They are especially useful for their action on the skin, being a capital combination of an opiate and a diaphoretic. Their use with children is dangerous; as they are prepared on a large scale, and often being not well mixed, they may contain much more opium than is directed.

Opium given in small doses produces first a feeling of slight exhilaration. This is quickly followed by a sensation of quiet, a subduing of restlessness, a dreamy half-sleep which may continue for hours. The state produced is not one of stimulation of the reasoning powers, but rather a kindling of the imagination. Where there is no especial desire for activity, sooner or later, depending on the patient and the size of the dose, he falls into a quiet sleep, which is not to be distinguished in any way from ordinary slumber. He awakes with a slight dryness of the throat, some depression, nausea and impairment of digestion. For a few hours also there is apt to be constipation. Some cases however show marked depression of spirits, excessive nausea and vomiting, weak pulse and muscular debility, instead of the usual symptoms I have just gone over. The vomiting is apt to be increased by any change in condition, even of the slightest. It is almost diagnostic of this condition that the patient is quiet as long as he is in a horizon-

tal position; but on attempting to rise this vomiting again comes on. In some cases this condition of depression replaces the ordinary symptoms entirely. In other patients severe pruritus is common when the action of opium is going off. This may be so pronounced that it forbids the use of the drug. In children, especially young children, opium, even in very small doses, frequently produces different symptoms, causing most pronounced depression.

The phenomena of a large dose are divided for convenience into three stages. These stages are not sharply marked; they glide into each other with no sudden changes. The first stage can be called for convenience "the stage of quiet excitement." There is no real increase in cerebral power; there is a cerebral stimulation only from the pleasant effects which are produced. There is the peculiar stimulation of the imagination in which dreams pass in endless quiet succession before the mind. If the dose be quite large, this stage may be correspondingly short. In those who are in the habit of taking opium, there may be frequently actual increase in intellectual power. Then appear the characteristic phenomena of the second stage. The respiration is slow and deep; the pulse is slow, full and strong; the body is warm and dry; the pupils are firmly contracted; the face is more or less suffused. There is abolition of all cerebral faculties, but not so complete that the patient cannot be aroused. No matter how profound the sleep may seem to be, the sleeper can be wakened up. This is an important distinction, which separate these cases from those of apoplexy. If a patient fails to respond to proper stimuli, you can be sure that a more deadly drug than opium is operating. The respiration, which is slow and full, gradually falls in rate, although on arousing the patient it is temporarily quickened. It drops from sixteen to twelve, to ten, to eight, to six, to four in the minute. The pulse comes down from seventy-five to sixty; rarely does it fall below fifty. It is still full and strong; but it does not have the great mighty stroke of the digitalis pulse. In the development of the third stage we have the same phenomena, modified by the appearance of exhaustion. The pupils are still contracted; the unconsciousness has become deeper; the respirations are distant, slow and feeble. The surface of the body is bathed in a cold, clammy sweat. The pulse is small, running and rapid. If nature is left to herself, these symptoms deepen; the respirations become excessively slow, interrupted by periods of death-like silence; the countenance grows more and more cyanotic, the lamp of life is flickering; as death approaches, the pupils widely dilate, as if to allow the soul to escape. Rarely is the course of the drug's action broken by storms —convulsions—in the Anglo-Saxon adult; they are more common in the Asiatic and in children.

We will study the symptoms produced by opium for the purpose of seeing the method of their production. They are connected with the respiration, circulation, nerve centres and the pupil.

First, the action on the nervous system. Its chief action here is as a paralysant to the cerebral cortex. It was formerly taught and believed that it produced congestion of the brain; all that we know is that the protoplasm of the brain-cells is affected by its active principle. Below the cortex, the respiratory centre is early affected; this is proved by experiments in which it was found that in animals the drug's effect was not altered by section or stimulation of the vagi, showing that its action is on the centre itself.

Second, the action on the circulation. Gscheidlen cut the pneumogastrics in an animal and gave opium, and the slow, full pulse was not produced: proving that the drug acts on the inhibitory cardiac nerves. It is also probable that it acts on the inhibitory cerebral centres, stimulating them. This is demonstrated by the instantaneous great fall in pulse-rate following the injection of a large dose of the alkaloid into the carotid—that is, into the inhibitory brain centres.

I will not go into any elaborate discussion of the experiments in regard to the action of opium on the pupil. The pupil is contracted by direct action on the oculomotor centres; the dilation as death approaches is due to paralysis of the same. I suppose that about twenty per cent. of you will tell me on a subsequent interesting occasion that in the third stage of opium poisoning the pupil is dilated; confusing this final phenomenon with the condition existing throughout the stage.

To complete the survey of the general physiological action, two points remain to be considered. In small doses morphine is a quieter of peristaltic motion; by large doses it is increased. More important is

the glandular action of opium; it acts in a most marked way on the whole alimentary tract, checking secretion and causing constipation. It is a desiccant from the mouth to the stomach and intestines. This makes it a marked factor in producing indigestion and checking the hyper-secretions of some forms of diarrhœa.

The fate of the active principle of opium in the body has been somewhat uncertain in the past. It is undoubtedly absorbed, as the alkaloid or as an alkaloidal salt. Professor Wormley has maintained that the methods used by many chemists who have reported its elimination through the kidney have been faulty. Recently, however, Professor Wormley, through careful review of the subject with the new tests for morphine has obtained evidences of that alkaloid in the urine. In cases of suppression of urine a new source of danger is apparent with opium in the system; being unable to excrete it, the kidneys throw it back into the circulation, renewing its poisonous powers on the economy. Again, in old people with weak bladders, in which there is great retention of urine, there is danger of re-absorption of the drug and its entrance again into the circulation. In severe kidney trouble, opium is undoubtedly a dangerous remedy. Its use in uræmia, for the production of diuresis, is not only ridiculous but decidedly reprehensible. Morphine thrown into the system from the bladder or the kidneys, seems to act with increased power on the economy.

The physiological action of morphine in general is similar to that of opium. The symptoms of poisoning are the same; the therapeutic action differs principally in the alimentary canal. Morphine is less of a desiccant, causes less nausea and constipation. It is about four times as powerful in its action as opium.

When an overdose of opium is taken, it is the old time-worn rule of thumb that the patient must be kept awake. But sleep, in itself, under the circumstances is not an evil; unconsciousness does not kill. As far as that goes, a patient might remain unconscious until old age, for all the evil effects it produces. The real fact is that death occurs from failure of the respiration; occasionally, if respiration could be maintained long enough, heart failure may happen; but the respiration always fails first. As unconsciousness deepens, the sensibility of the respiratory centres grows less. Consequently involuntary breathing becomes less perfectly performed. Moreover, when kept partially awake, the patient suffering with opium poisoning can be made to supplement the almost suspended involuntary breathing by voluntary efforts. Hence, there is one overwhelming indication to maintain the respiration. First, evacuate the stomach of its poisonous contents. If possible do this with an emetic. But, in view of the fact that the peripheral nerves have been benumbed by the action of the drug and the sensibility of the centres in the medulla have been diminished, a powerfully stimulant emetic is the only one of service. The so-called mechanical emetics are good, and but little depressing: sulphate of copper, or, better, sulphate of zinc or mustard. Mustard flour is generally found in the household, and is efficient. A large tablespoonful in a tumblerful of warm water should be given at once; and the dose repeated in fifteen minutes until effective. Thirty grains each of sulphate of zinc and ipecacuanha may follow; to be repeated once or twice. Large draughts of warm water should be administered in the intervals and between the vomitings, to wash out the stomach. If this should fail, then the stomach-pump should be used. It is of no service when the opium has been swallowed in solid form. A fountain-syringe with rectal tube removed, or, in an emergency, a rubber gas-pipe may be used. The external end is elevated after the other end has been passed into the stomach; water is poured into the tube by means of a funnel until the stomach is full; then, without the tube being allowed to empty itself, it is depressed, when the flow of water will be reversed. Maintain the bodily heat as in other forms of narcotic poisoning. Arouse the patient chiefly to maintain the respiration. The breathing is fuller and faster when the patient is awake, and conscious effort is added. It is often surprising how an apparently unconscious man will keep on breathing at the word of command. Walking, shaking, shouting, flagellations with fine twigs are all measures to be used. But remember you can walk your patient to death; you can easily bring on exhaustion, which only increases the odds against his life. I have seen cases beaten black and blue under this treatment. It is wrong. The natural prostration of the third stage is easily increased. I wish to call attention to the intense irritation produced by the Galvanic or Faradic dry brush. This is an agent

which is strongly helpful in preserving consciousness; it is not depressing or exhausting, and leaves no trace behind. Attempts to polarize the phrenic nerve are useless.

The cold douche is an excellent method of restoring consciousness, stimulating at the same time the respiration. Supporting the head and shoulders over an ordinary wash tub and dashing on them ice-cold water, and water a little hotter than the hand will bear alternately, is good in its effects. There are two depressing factors in the system, the opium in the blood and the increased amounts of carbonic acid from the imperfect respiration.

There are three substances which are useful as agents for respiratory stimulation. In the early part of the century when I sat on the students' benches, it was taught that coffee did good by keeping the patient awake. The fact was true; the theory was useless. The chief good done by coffee is its stimulation to the respiratory centres. Coffee is preferable to caffeine because the empyreumatic oil which it contains is more efficient in preserving consciousness, and in this indirect way aiding the respiration. Hence unlimited quantities of black, strong coffee should be poured into the patient. Atropine as a respiratory stimulant is of the greatest importance in opium poisoning, when there is evidence of failure of respiration. There is no antagonism, in the strict sense of the word, between opium and atropine in their respective action on the eye. Opium contracts the pupil by influencing the nerve centres; atropine dilates the pupil by acting on the peripheral nerves. Hence when you are told to watch the eyes in giving atropine in opium poisoning, you have no safe guide. The proper thing to do is to watch the respirations. Giving no more of the drug than is necessary, for fear of the addition of atropine poisoning to that of the opium, and yet not afraid of its administration is the correct course between Scylla and Charybdis. Do not give large doses, but frequent doses. A fiftieth or fortieth at once, followed by a sixtieth in fifteen, twenty or thirty minutes. As the respirations grow more frequent, withhold the drug. Strychnine should be of service; but it is rarely used. Again, alcohol, in the stage of depression, sustains the arterial circulation. The bodily temperature can be maintained by the use of external heat.

Whenever life is seriously menaced, artificial respiration should be resorted to. For this purpose a bellows and tube are required. From twelve to fifteen times a minute the lungs should be filled a little fuller than naturally. Tracheotomy has been suggested for the insertion of the tube, but it is unnecessary. All that is needed is some form of face mask that will cover both mouth and nostrils. The ordinary form used by dentists in nitrous oxide gas inhalation is the best and simplest for the purpose. Transfix the tongue previous to its use with a needle and hold it out by the accompanying thread. If you find that the lungs fail to expand, insert the ordinary tube used in intubation. I believe that by these means nearly every case can be saved; life being maintained until the alkaloid is eliminated.

The first indication for the use of opium is for the relief of pain. Of all the remedies that we have as analgesics, the anæsthetics and opium are the only true examples. The anæsthetics are used for the pains in which the agony is short, but while it lasts is so great that it seriously threatens life by paralysis of the vital functions. Opium, on the other hand, is used where there is any permanency to the pain. In neuralgias and chronic disease, it should be used with the greatest reluctance, for fear of the formation of the opium habit.

The second indication is to produce sleep. Formerly opium was the king that reigned supreme in this kingdom; but the territory has been invaded by many newer drugs. So that now, practically, opium is not used for this purpose, except in the sleeplessness caused by suffering. In confusional insanity, especially that form called delirium tremens, it must be used with care, so as not to overwhelm the nerve centres. Even here other remedies are more highly esteemed. In certain low fevers it can be advantageously employed. For the restlessness and insomnia of typhoid it is among the safest agents; and yet there is an almost universal prejudice against its use here. It is often combined with chloral with excellent results.

Thirdly, to allay irritation. In sudden attacks of hemoptysis, the morale of the patient is always upset; the spitting of blood is regarded by the laity as pathognomonic of phthisis, and phthisis means death to them. Again, it is of service in great mental shock of any form. In great peripheral irritation, as in confluent small-pox, where the patient is tortured with untold agonies, its use is indicated. Beyond the relief of pain there seems to be a sustaining power in

opium produced by benumbing the centres of organic life; hence in widespread inflammations where systemic collapse is threatened, opium exerts a life-saving power. There was a time when the universal treatment of peritonitis was the administration of opium. It is good treatment beyond all doubt in proper cases, and is still largely used. In sthenic cases, depletion by leeches or bleeding should be employed at the outset; or the depletion can be obtained by free purgation with saline purges. I remember one case, a third-year medical student, who had just passed his final examination. Run down in health, he had taken the opportunity between examination and commencement to work in his garden when the weather was cold and blustery. Shortly afterwards he was seized with a furious abdominal pain, agonizing in its intensity. He lay in this condition when I was called to see him. I immediately ordered his abdomen to be covered with as many leeches as would cover it; following this up with liberal use of calomel and opium. Speedy amelioration of the symptoms followed, with subsequent recovery. The opium, to do good, must be given in doses to get the systemic effect: the patient must be more or less narcotized. Closely allied to its use in peritonitis is the service of opium in severe enteritis, where there is a paralytic condition of the muscular coat of the intestines. Here constipation from obstruction occurs. The use of irritant purgatives only serves to increase the trouble. Opium, by allowing the muscular coat to be relieved from spasm, apparently acts as a cathartic. One case of this sort comes to my mind now. A woman ate corned beef and cabbage for dinner. She probably indulged in it for dessert, and undoubtedly enjoyed it for supper, serving up what was left for breakfast. A furious abdominal pain, with obstinate constipation appeared. She was filled with irritant purgatives, all without effect. She remained obstinately constipated. On seeing her, I learned that, for the first twelve hours, she had spent the time in leaning over a chair back, pressing it into her belly. When I saw her she was on her back, with her knees drawn up. The handwriting on the wall was there, if any one would but read. The first pain was the spasm due to the cramp of the intestines, which was relieved by pressure; the second pain, intolerable in its character, was the lighting up of inflammation. The lulling use of opium and the application of leeches brought about a change. Profuse alvine discharges began. Then began a terrible struggle for life, in which the woman finally won. Castor oil, to bring away the contents of the bowel, in these cases is a pleasant non-irritant laxative, which is generally effective. In acute vomiting—hyperemesis—opium is our best remedy, especially if irritation is present. In more chronic forms, its administration should be made more reluctantly. As an anti-emetic, it is best given by the rectum, in suppository or injection. The extract of opium is soluble in water and free from narcotine, making it the preferable preparation. In irritant poisoning in the gastro-intestinal tract, opium is indicated after the antidote.

Opium is used to check secretions. In bronchitis opium checks secretion. Nature's method of curing this disease is by free secretion; so beware in giving opium in this trouble. Only give enough to relieve unnecessary and exhausting cough, never checking the cough unless it is out of proportion to the results. In ordinary cases of bronchitis it is better not to give the drug, reserving it for irritable subjects. To check the excessive secretion in diarrhœas, opium is useful, and it is often curative in its results when the exudation is excessive or is imperiling strength. It is combined usually with other agents. In dysentery it is used rather to relieve pain and tormina than for decrease of the secretions. Cold water, ice or iced water is a useful adjunct. In diabetes opium is useful. In diabetes insipidus other remedies are of service, but in the mellitus form it is imperative that opium in some form should be given without regard to the formation of an opium habit. Given continuously and in large doses, it acts on the nerve centres, checking sugar formation.

Opium is valuable as a sudorific. In the shape of Dover's powder, opium is largely used in the forming stage of muscular rheumatism, or of a "cold." In "soaking the feet"—which is a domestic term for a pedilurium—we find we have a valuable aid to sudorific remedies. The patient is undressed; his limbs are immersed to the knees in hot water simply, or water containing mustard flour. In five minutes, more water, a little hotter, is added until the expiration of twenty minutes. Then the patient is bundled off to bed. Previously a Dover's powder has been administered; and on being placed in bed, the patient should drink one or two tumblerfuls

of a very hot and strong lemonade, containing one, two or three tablespoonfuls of whiskey or brandy. Care must be taken to avoid any exposure for a day or two. Anointing the skin with the oil of sweet almonds or some other bland fat appears to have some power in preventing the deleterious effects of cold after sweating.

In the administration of opium, each preparation has its peculiarities. The pill of opium, kept in the drug store for any length of time, dissolves out slowly in the alimentary canal. It should, therefore, never be used to produce a profound constitutional effect. On the other hand, for this reason many practitioners prefer this form for action on the intestines; the pill reaching this point practically unaffected. Paregoric should never be given except when its constipating influence is desired. Children bear opium badly. Never give more than one-third of the dose for children as indicated by Young's rule. Never press its use, as in the adult, lest there be developed a tendency to sudden collapse; or to convulsions.

Chronic opium poisoning—commonly called the opium habit, deserves our attention. I believe that it is much more common in the extreme Western States than it is with us. It is far worse than the alcohol habit. There is nothing diagnostic about the symptoms. There is, perhaps, perpetually a little ill-health, without apparent cause. The symptoms are bizarre and irregular. There is haziness about the patient's actions; his normal sense and faculties are clouded; he is given to false statements or to prevarication; in other words he is a great liar. Never imperil your reputation by endeavoring to treat such a patient unless he is so placed that you have entire charge of his life. *Habitués* will come to your office and swear they are not touching a grain of opium; they will gladly pay you big fees; and yet all the time they are revelling in the drug. They will corrupt nurses and attendants by bribery if placed under surveillance. There are three ways for the withdrawal of the drug: first, taking it away at once; second, withdrawing it in from five to ten days; and, third, taking months for its removal. If it is done abruptly there is danger of collapse, excessive malaise, insomnia, complete loss of appetite, vomiting, terrific diarrhœa and general checking of secretions. When seven to ten days is the limit set for its withdrawal, I have never seen a case that produced symptoms that could not be controlled. The slow method, I believe to be uncertain in its results. Proper feeding is of great service in relieving distressing signs. The use of electricity is good, not only for its effect on the system, but also to distract the patient's attention from himself. Massage serves the same dual purpose. For the diarrhœa, bismuth and carbolic acid are the best remedies. External warmth, hot drinks, broths, stimulating easily-digested food, are indicated. Bromide of potassium, quinine, etc., can be employed as needed. In withdrawing the drug it is better always to deceive the patient as to the quantity of the drug which he is getting. There are various methods for this purpose. When the morphia is taken hypodermically, it can be gradually replaced with distilled water in the injection. When morphia is taken by the mouth, make it up with quinine; this disguises the taste, rendering it impossible for the patient to judge the amount he is receiving. Quinine is an excellent tonic, the powders are kept the same size, quinine gradually replacing the morphine. I had a lady sent me who was taking paregoric. Here we had a mixed habit. She was drinking three pints of paregoric a day. This is equivalent to about a pint and a half of brandy. I ordered her a bottle of paregoric of large size. The druggist also made a similar bottle of paregoric, only the opium was left out. As fast as she drank the regular paregoric the bottle was kept filled from the spurious preparation. In this way the opium was practically out of her bottle in a week's time.

COMMUNICATIONS.

TREATMENT OF GANGRENOUS WOUNDS AND DISEASES.[1]

BY BEDFORD BROWN, M. D.,
ALEXANDRIA, VA.

Many years ago before the late war I determined to institute a series of experiments to ascertain the capability of local and general treatment of all gangrenous wounds and diseases that came under my care either for the prevention or for the arrest of the extension of gangrene.

[1] Synopsis of a paper read before the Southern Surgical and Gynecological Association, at Atlanta, Ga., November, 1890.

The object was to find local agents possessing active properties as stimulants of vital action in the affected parts, also as means of disinfecting and deodorizing gangrenous sloughs, and of hastening their final separation, and the establishment of a healthy basis for granulation. In cases coming under my care I found the old deodorizers fail to accomplish these objects. I then employed a concentrated solution of zinc sulphate and dilute sulphuric acid as a local application which seemed to meet all the requirements. The first case in which it was applied was in the following formula.

℞ Zinci sulphatis . . . . . ℥i
Aquæ . . . . . Oi
Acid. sulph. dil. . . . . f℥ss
M.

After the free application of hot water, the solution was applied every three hours on raw cotton. In the course of two days the sloughs separated rapidly, leaving a perfectly clean, healthy basement for granulation. This solution evidently possesses active antiseptic properties. It is an admirable deodorizer, it is clean and it cleanses the parts effectually.

In cases of great loss of sensibility in the parts, weak circulation and reduction of vital action, I know no agent better calculated to arouse nervous activity and dormant vitality; for as soon as the sloughs are removed and the living tissue is exposed, it gives rise to intolerable pain. I have used this solution with benefit in all forms of gangrenous affection and wound, some limited, others extensive and associated with septicemia. It possesses no caustic property, and it contracts and shrinks the sloughing tissues rapidly, while its action on the living tissues is to stimulate renewed action and sensibility where the capillary circulation is languid, the vaso-motor action sluggish, the circulating blood about to become stagnant.

During the late war I had frequent opportunities of using this preparation, and since that time also. It was cheap, abundant, easy of application and exceedingly cleanly, and did good service in my field hospital practice in the Confederate Army.

Another most admirable antiseptic, disinfectant and stimulant of vital action, found by me invaluable in the local treatment of gangrenous affections, is bromine in solution. In cases of infectious gangrenous inflammation such as hospital or gangrenous erysipelas, where the process is propagated by an infection, bromine is especially applicable, as it destroys the infection, subdues the peculiar infectious inflammation and in this manner prevents mortification. However we may differ in regard to the peculiar nature or form of infection that causes gangrene of the infectious variety, it is a fact well established that bromine is one of our best correctives. I have in too many instances seen it correct sloughing wounds and diseases, by subduing inflammatory action and destroying the infection to doubt it for a moment. I have used these different preparations alternately with benefit.

I have used, advantageously, hot-water applications from 110° to 120°, made to the parts for fifteen minutes every one or two hours. Sterilized water at this temperature is grateful to gangrenous parts. Cool applications are unpleasant, because of the chilliness they impart. In one of my cases the patient was not satisfied when the water was below 130°

I have used hot water on unhealthy wounds, with feeble circulation and reduction of neurosis and vaso-motor action, before or after the development of sloughing, for more than forty years, both in civil practice and during the late war in field hospitals. I saw this practice thoroughly applied and tested in the surgical practice of my preceptor, the late distinguished Dr. Benjamin W. Dudley, of Lexington, Ky. He applied hot water, that had been boiled and then reduced to the proper temperature, to all wounds of an unhealthy character and to all sloughing affections and always with benefit.

I have repeatedly seen Dudley apply hot water that had been boiled and reduced to 105° to the eye in cases of violent purulent ophthalmia, with the effect of subduing the engorgement and inflammation and of preventing that most untoward misfortune, sloughing of the cornea. This was more than forty years ago. I have never seen sloughing of the cornea where this method was faithfully carried out.

One of the chief objects in treating gangrenous affections and wounds is to improve the condition of the blood, to strengthen the circulation and to counteract the tendency to collapse. Hence the importance of general sustaining treatment. An abundance of nutritive food, alcoholic stimulants, invigorating and vitalizing remedies I have seen, in army and private practice, tide over forlorn cases, that would otherwise have died. Gangrenous patients—provided

the stomach is in good condition—can take large quantities of alcohol with benefit. I have given ten grains of carbonate of ammonia and two ounces of whiskey every one or two hours with marked benefit in establishing reaction in the threatened collapse from gangrene, and in pyemic fever. In those cases of gangrene arising from embolism or thrombosis I have found carbonate of ammonia, strychnia and nitro-glycerine with iron the best combination for establishing a collateral circulation in connection with alcoholic stimulants and nutritious food. In cases occurring during recent years in my practice, I have found nitro-glycerine, in connection with the remedies mentioned, do well. I have observed in sloughing affections that as soon as disinfection of the diseased tissues by the action of bromine or the zinc and sulphuric acid solutions has been effected, the condition of the general system responds promptly and not before. Hence in treating the sepsis of gangrene we must ever be active in cleansing, disinfecting and stimulating the vital action at the seat of the local lesion.

The following cases are examples of what may be effected by the treatment of gangrene by the method just described.

Case 1. Gangrene of the external genitals in the female. I was called to see this patient many years ago. She was a married woman in indigent circumstances. The patient had been delivered by a midwife about a week before. The entire external genital organs, from the mons veneris to the perineum, or very nearly to the anus, including the labia, nymphæ and fourchette, were in a state of gangrene. The organs were enormously swollen, black and pultaceous, and emitted an ichorous discharge that filled the apartment with an intensely fetid odor. In this case hot-water applications were made, at 120°, every three hours, and after each application the saturated solution of sulphate of zinc and dilute sulphuric acid was applied on raw cotton to the parts. The tincture of iron, stimulants and nourishment were administered freely. In forty-eight hours the gangrenous parts had separated and sloughed off, leaving an entirely clean, healthy surface, ready for granulation. All offensive odors had disappeared and the serious symptoms of septicemia, which threatened the patient, subsided in due time.

Case 2. Hospital gangrene of the foot. This was a sequel of a severe gunshot wound, causing an extensive lacerated wound and shattering all the metatarsal bones. This patient, when brought into his field hospital, after one of the great battles near Richmond, had all the symptoms of gangrene, which was rapidly extending towards the ankle. Hot-water applications were made every two hours, and the foot was enveloped in raw cotton saturated with a solution composed of sulphate of zinc, ℥j; water, Oj; dilute sulphuric acid, f℥ij. This was reapplied every three hours. Stimulants, nourishment, iron, quinine and carbonate of ammonia were prescribed. Although the patient's strength was greatly exhausted and he had symptoms of pyemia, he rallied, the gangrene ceased, the sloughs shrivelled and separated, the offensive odor subsided, and a healthy basis remained. The extensive wound finally healed.

Case 3. Dry gangrene of the foot. The patient was a man, 56 years old, whose foot became inflamed, swollen and painful from probable contusion of the popliteal artery, as no pulsation could be detected in the tibial or perineal arteries. The patient had been subject to carbuncles, the probable cause of thrombosis. The gangrene covered the entire foot and toes, except the plantar surface. The general condition of this patient was bad, his pulse was feeble and frequent, and his complexion sallow. There were rigors and fevers daily, with copious night-sweats, great depression of mind, and total loss of appetite. After the various gangrenous tissues, including the skin, muscles and tendons, down to the periosteum had been dissected away, this was found to be gangrenous also. Neither Surgeon-General Hamilton, who saw the patient, nor I could detect pulsation in the arteries below the popliteal. Hence the inference was made that there existed embolism of that artery, and that a feeble collateral circulation existed below that point, not fully capable of supporting the limb. Dr. Hamilton thought amputation would be necessary. But the patient was given the full benefit of conservative surgery. He was ordered the tincture of the chloride of iron, in thirty-drop doses, the hundredth of a grain of strychnine, the same quantity of nitro-glycerine, and three grains of quinine every three hours for the purpose of arousing vaso-motor action, establishing a better collateral circulation, and arresting the gangrene. He took also an abundance of stimulants and nourishment. The concentrated solution of zinc sulphate and dilute

sulphuric acid was applied to the gangrene, also frequent hot-water applications at 130° to the parts. The aspect of the gangrenous parts improved under this treatment, but at certain points where the sloughs had separated the solution excited intense pain, and its use was discontinued. A solution of bromine, containing f℥ij to the pint of water, was substituted. The bromine application was exceedingly soothing, and acted as an admirable antiseptic, disinfectant and stimulant of vital action. The gangrenous inflammation was duly subdued; the local infection was corrected, and the extension of the gangrene was arrested. When all the sloughing tissues had separated and been thrown off, a clean base was left, with a fair degree of circulation. But a portion of the tarsal, and all the upper surface of the metatarsal and phalangeal bones was exposed. Under the local and general treatment, granulation developed rapidly, healthy, vigorous and full of florid blood, indicating, if the conjecture was correct, that a sufficient collateral circulation had been established to arrest gangrene and repair damages. All the exposed bones were finally covered with newly formed tissue and the large wound healed perfectly. But it appeared subsequently that at several points, more particularly the articular surfaces of the formerly exposed bones, there was necrosis, causing ulceration of the newly formed tissue. To these points of necrosis, applications were made daily of dilute muriatic acid of the official strength. This has been my method of treating necrosis of bone for some years, and the results have been good. It is surprising how rapidly the phosphates and carbonates of lime in the necrosed bone are converted into the soluble chlorides, and disintegrated and dissolved by the action of the acid. After disintegration of the bone at these points, granulation would again form and heal over the opening.

Case 4. Phagedena. This was a case of gangrenous phagadena from chancroid. In this case there was gangrene of the prepuce, of the glans penis and skin on the dorsum. The general condition was bad. The local treatment consisted in frequent hot-water applications, followed by a solution containing zinc sulphate, ℥i; water, a pint; dilute sulphuric acid, f℥ii. The patient took internally thirty drops of tincture of iron and five of muriatic acid every three hours, with stimulants and nourishment. In the course of two days the offensive odor had ceased, the gangrene had been arrested, the sloughs were cast off, and a healthy base was exposed. The glans, prepuce and skin on the dorsum sloughed off, and the parts healed ultimately.

Case 5. Gangrenous carbuncle. The carbuncle in this case was very extensive, covering the entire back of the neck, from the scalp to the sixth cervical vertebra. The entire mass of tissue became gangrenous down to the spinous processes of the cervical vertebræ, including the muscles and tendons. The patient lost the power to a considerable extent of extending the neck. A solution consisting of sulphate of zinc, ℥iss; water, a pint; dilute sulphuric acid, f℥ss, was applied on absorbent cotton every three hours; and, as the condition of the patient was extremely prostrated, tincture of iron, quinine, strychnia and nitro-glycerine were given every three hours. The local and general treatment enabled the system to arrest the gangrene, throw off the sloughs and finally to heal the large deep cavity.

In conclusion, I would urge discrimination in the adaptation of the method of treatment adopted in gangrenous affections to the variety, form and origin of the disease. There are types of gangrene purely septic in origin, in which the sublimate dressing is thoroughly applicable. There are other cases, such as hospital or camp gangrene or gangrenous erysipelas, in which the bromine treatment surpasses all others. Then, also, there are cases of either a traumatic or idiopathic form, in which the vital and vaso-motor functions of the parts are paralyzed and there is no tendency to establish the line of demarcation, and the tissues are rapidly broken down. Here a potent stimulant to vital action is needed, as well as an antiseptic, such as the strong solution of zinc sulphate and dilute sulphuric acid.

Care of the Insane in New York.—Since the murder of Dr. Lloyd by a lunatic, a new order by the State Commission in Lunacy states that no insane patient in the custody of an institution must be allowed to go out on parole who, in the medical superintendent's judgment, is dangerous to himself or to others; that no parole shall be granted for a period longer than thirty days; and that, on the escape of a patient, prompt and vigorous measures must be taken to secure his return.

ANTISEPTIC MIDWIFERY.[1]

BY A. S. MAXSON, M. D.,
MILTON JUNCTION, WISCONSIN.

The antiseptic treatment of the puerperal condition originated from antiseptic surgery and has developed with equal rapidity. Although the statistics show a remarkable progress in the reduction of puerperal septicemia, many an excellent practitioner is rather skeptical regarding the method. Dr. Leopold reports, out of three thousand one hundred and ninety-six women confined in the Dresden Hospital between May 1, 1884, and Sept. 1, 1886, four deaths from septic infection, or .12 per cent. Dr. Invoeffs, from Moscow, reports seven hundred and fifty-six labor cases, with no death from septic poisoning. In the Russian, German, Bohemian and Austrian hospitals, the septic death rate was 1.3 per cent. between 1874 and 1884; but since 1884 it has diminished to .42 per cent. During the year 1888, four hundred and sixty-six women were confined in the Boston Lying-in Hospital, with the death-rate of but one from septicemia, or .22 per cent.

The use of antiseptics in private midwifery practice in Germany is compulsory by law. Cullingworth says that "puerperal fever, both in its fatal and non-fatal manifestations, may be practically stamped out." Of course, the method of working must depend upon a correct understanding of conditions and methods of infection.

A. Döderlein, of Leipsic, has made a very important experiment regarding germs in the lochia of normal puerpera and the septic condition of young mothers. He says: "Under normal conditions the lochia from the uterus contains no fungi, while that from the vagina contains numerous germs of different kinds. The lochia from the uterus can, under normal conditions, be injected into animals without producing any reaction, while that from the vagina may produce abscesses. The existence of germs of any kind in the puerperal uterus will, as a rule, cause elevation of temperature. After the temperature has fallen, it will be found that the lochia from the uterus is again free from germs. . . . The lochia from the uterus of fever patients will produce appearances of infection in animals. Only in those cases where there are so few germs that the febrile disturbance is slight will the lochia produce no effect in animals."

As to the kind of antiseptic used, there is much diversity of opinion. Corrosive sublimate, one of the most efficient germicides, has caused poisoning in a number of instances. I feel, as Dr. Wm. L. Richardson says: "While many authorities are willing to admit the superiority of corrosive sublimate as a germicide, not a few, however, hesitate to recommend its adoption in general practice, owing to the danger of mercurial poisoning." From the sublimate vaginal douche, Maurer has reported death. Dr. Emile Blanc is quite apprehensive regarding the sublimate vaginal douche, but still thinks best to continue its use except in cases of post-partum hemorrhage, renal disease and anemia, where it should be displaced by carbolic acid. The strength of the sublimate injections has, from the time of their introduction, been gradually reduced in strength by Stadtfeld and Sänger and others from 1 in 1,000 to 1 in 2,000, then to one in three or four and, now five thousand, with one in eight thousand in post-partum hemorrhage, etc. The *Annual* of 1890 reports twenty-two cases of sublimate poisoning.

The danger of poisoning has been sought to be obviated by a post-sublimate injection of a 2 to 3 per cent. solution of carbolic acid, or by pressing the perineum down, so that all the sublimate injection will run out, or by turning the patient on her side or raising her up. All these means are recommended by renowned men. Fearing the possible effects of active poison in vaginal or uterine injection, and considering their inconvenience, I diverged from the path of my fellow-practitioners. I have recently found that others have done likewise, but used different medicines. Two years ago I used corrosive sublimate, 1 to 2,000, or carbolic acid, 2 per cent., for vaginal injection both before and after delivery. This I followed with antiseptic pads made out of napkins dipped in 1 to 1,000 sublimate solution and dried. In from one-half to two-thirds of the cases the lochia would remain without putrefactive odor throughout the course of the puerperium, and there would seem to be no fever.

Still fearing my injections, and being dissatisfied with their results, I used a creoline injection of 1 per cent. mixture, either just before, or before and after labor, and sopped

[1] Read before the Central Wisconsin Medical Society, Sept. 30, 1890.

the vulva with creoline mixture once in from six to eight hours, and used sublimate cotton on the napkin next to the vulva. The results have been quite satisfactory to both patient, nurse and myself. The lochia has remained free from the odor of decomposition throughout its course. The temperature has remained normal to within one degree. The rise of temperature does not always depend upon septic poison or inflammation, for I have noticed some cases to have a rise of one degree or less immediately after labor, and in twenty-four hours the temperature was normal.

CASE OF A HERMAPHRODITE.

BY D. J. TILLOTSON, M. D.,
BUFFALO, N. Y.

To the embryologist and the anatomist there is probably nothing in the line of human monstrosities of greater interest than the hermaphrodite, true or spurious; but the physicians of the present time have hardly given this subject as much attention as did those of the past, and it would seem that, with the increased power of observation given us by the microscope and the many new rays of light that have been thrown upon the subject of embryology, the entangling of that group of cells in the embryo which eventually become the internal and external genital organs would prove a subject of which much might be learned and written from both a demonstrative and a speculative point of view.

In the history of noted cases of hermaphrodites, much that is interesting has been related; and, aside from the popular interest attached to these individuals, we may learn much that will guide us in our advice regarding infants born in this condition. In these cases our opinions are asked when we least expect it, and our conclusions must be arrived at quickly. These conclusions often decide the future of an individual, and should our decision chance to be wrong, in after years it may humiliate the family and the person, and ruin the reputation of the physician in that community; for what woman would employ an obstetrician who would be guilty of incorrectly diagnosticating the sex of her child?

It is not the object of this article to dwell upon the whole subject of hermaphroditism, but to present and describe one case, which the writer was called to see within a month after his graduation in medicine.

On April 26 I was called to attend a boy said to have colic. I found my patient to be a child four years old, bright, and to all outward appearance a vigorous, healthy boy. He had a disposition when well to romp and play and to engage in boyish sports. In figure he presented all the characteristics of a boy of his age. He had a large head, heavier features than a girl of same age, broad and square shoulders, full chest and a pelvis narrow in comparison with the shoulders. I think one would be inclined to pronounce it of the male rather than of the female type.

On raising the little fellow's shirt, to palpate his abdomen, I discovered the state of the external genital organs, and made a thorough examination of the same. The mons veneris was very prominent, broad and rounded, and contained an abundance of adipose tissue. After careful search in the regions of Poupart's ligament, neither inguinal ring, spermatic cord, testicle nor ovary could be found—the result in that direction being perfectly negative. From the mons, two ridges covered by integument extended backward and downward exactly like labia majora, fading away before they reached what would be the posterior commissure and *fourchette*. These were covered by true skin, except on their inner and upper portion, which was true mucous membrane. Upon careful manipulation of them nothing was revealed but the characteristic feel of adipose tissue. From between the labia, and from the normal position of the clitoris, protruded an organ which was one and one-half inches in length in the flaccid state, and two inches long during an erection. At the proximal end it was half an inch in diameter, triangular in shape, gradually tapering to the distal end, where it was the size of a slate pencil. About two-thirds of this organ was covered with true skin, which was movable, but not to the extent of that of the normal penis. The outer third was covered with what was probably originally mucous membrane, but had become thickened, presumably by friction on the clothing. It was dull red in color. There was no glans, no prepuce, no corona. On the tip it was perfectly smooth, even possessing a notch or dimple where the meatus urinarius would naturally be, if the organ were a penis.

This organ was oval in shape—its anterior

two-thirds being flattened on both superior and inferior surfaces, and was evidently made up of corpora cavernosa. About one-half inch from the body, and on the inferior surface, was a slit about four lines in length, and it was through this opening that the child urinated. Only as far as this slit could the corpora spongiosum be felt. The child was unable to urinate in the standing posture without soiling its clothing, and insisted upon assuming the squatting position when passing water.

Between the labia, and below this penile organ, was nothing but a slight concave surface, covered also by true skin, which over its whole extent was dense and resisting to the touch and appeared to be of the same structure and a part of the perineum. Along either side of this clitoris, or penis, and for about one-half its length and extending over on to the internal aspect of either labium, was a row or line of small nodular bodies, reminding one of the carunculæ myrtiformæ. It occurred to me that these might be the remains of some structure which had at some time been removed; and, on questioning the mother, she said a doctor had cut something which he said would make the child "all right." But the mother could not tell what was cut. From the position of these ridges I should judge the organ had been bound down by some membrane, and was released by the operation, or that a structure analogous to the nymphæ or labia minora had been cut away.

An examination per rectum, to try to detect the internal arrangement of the organs, could not be obtained.

In presenting this, my first medical article to the members of the profession, I beg their indulgence, which I know they will willingly grant. This case being one of my first, and believing it to be of more than ordinary interest, I decided to give it to the profession.

I wish here to acknowledge the kindness of Dr. A. M. Ross who is ever ready with pencil and pen to aid in the advancement of the cause of medicine.

Can any operation benefit this child?

CASE OF TROPHIC AFFECTION OF THE THIRD PHALANGES.[1]

BY E. H. COOVER, M. D.,
HARRISBURG, PA.

On October 22, 1890, Mrs. D., thirty-six years old, consulted me about a very singular affection of the third phalanges of both hands. After a careful examination of the case, I admitted to her that her condition was both peculiar and new to me. Two days later she consulted me again. Just as she came in the office I was reading, in the *Journal of the American Medical Association*, October 18, 1890, an abstract of a paper by Rosenbach on an "undescribed trophic affection of the third phalanges," taken from the *Centralblatt für Nervenheilkunde*, August, 1890. Rosenbach claims to have discovered a hitherto undescribed trophic disturbance in the third phalanges. My case is a typical one, as described by Rosenbach, who says: "The disease consists essentially in an enlargement of the tubercle at the base of the phalanx, preceded and accompanied by pain in the part." Rosenbach says the disease is found almost exclusively in women from 30 to 50 years old, and is especially frequent in those approaching the climacteric. He has seen one or two cases in men, but it is relatively very infrequent in them as compared with the number of cases occurring in women. The disease, he says, is usually symmetrical, attacking both hands in the same way, and it confines itself strictly to the dorsal side of the third phalanx, the thumbs always remaining sound. It is preceded and accompanied by changes in the sensibility, formication, heat flushes, numbness, etc., in the region of the ulnar and radial nerves. In my case the joints are enlarged, the dorsal muscles of the third phalanges are atrophied, although the skin has a perfectly normal appearance. The radial and ulnar pains often extend to the elbows. There is some difficulty in grasping and holding small objects, unless the patient is looking at them; as soon as she turns her eyes from the objects held, she is liable to let them drop. The thumbs are not affected.

Rosenbach attributes the affection to trophic disturbances in the nervous supply of the periosteum, similar to the special

[1] Read before the Dauphin County Medical Society, November, 1890.

changes in the nerves of the skin, found in herpes. The differential diagnosis lies between arthritis deformans and gout. The first is distinguished by a very different localization—in the large joints and in the thumb, by the irregularity of the swelling, and by the involvement of the joint's surfaces, which remain free in the trophic disturbances under consideration. Gout is less easily differentiated; but we have the general diathesis, and above all the slow increase in the enlargement, without redness or swelling of the parts; while the peculiar local nervous symptoms are wanting.

The case which I saw was to me both peculiar and interesting, and as such I give it to the profession in general.

In regard to the treatment—I first administered tincture of nux vomica, and the improvement was slow. I then gave the patient nux vomica and phosphorus, which improved her condition more rapidly. With this medication, combined with a good nourishing diet, and the avoidance of severe muscular exercise, the patient's hands are growing steadily better.

New York Correspondence.

NEW YORK LETTER.

New York Academy of Medicine.—Ankylosis of Jaw.—Gonorrhœa and Stricture at three years of age.—Remarkable Extra-uterine Pregnancy.—Peritonitis in Infancy.—Rare Fracture of Clavicle.—Applying Plaster Jacket.

The Section work at the New York Academy of Medicine during the week ending November 15, presented several points of interest. In the Section on Surgery the Chairman, Dr. Robert Abbé, showed two patients upon one of whom he had operated ten years ago for anchylosis of the jaw. The result had been restoration of the function, immediate and permanent. His second case was that of a young woman who, for fourteen years, had been unable to move her jaw, food being pressed into the mouth through the gap left by two absent incisors. Dr. Abbé hoped to get good results from operative interference in this case also, but thought that the only method worthy of adoption was to cut down from without and remove a wedge-shaped segment of the inferior maxilla. This would ensure a good false joint.

Dr. Abbé also reported a case of gonorrhœa in a boy three years old, followed by tight urethral strictures six months later, requiring internal and external urethrotomy. The patient, an otherwise healthy child, was brought to him suffering with incontinence of urine, pain in the urethra and a slight discharge resembling gonorrhœa. Nine weeks before, the child had been tampered with by a young woman, who had been rescued from the streets and given occupation in the house of the child's parents. Within two weeks, he had a swollen penis, urethritis, incontinence and pain. The child was treated by urethral irrigation of a 1:8,000 bichloride of mercury solution. Gonococci were found in the discharges. Cure had followed in a short time. Six months subsequent to his being sent from the hospital cured, his mother had noticed him in great agony vainly trying to pass water. He was again brought to the hospital, when his urethra was found impassable even to the smallest instrument. His bladder was aspirated and about one and a half pints of urine was withdrawn. Aspiration was repeated until the third, when examination under ether showed three anterior strictures and one tight one at the membranous portion of the urethra, the latter only just admitting a filiform bougie. The strictures were dilated gently, but the deep one was so dense that urethrotomy was resorted to. The anterior ones were cut up to No. 22, French, with the Otis urethrotome. It was found to be a tough gristly stricture. Perineal drainage we continued for two days, when a No. 24 was found to slip painlessly into the bladder. After the seventh day all the urine had passed through the natural channel.

Dr. W. W. Van Arsdale said he had met with a great many cases of what he believed to be gonorrhœa in very young children. He had seen three during the past month. The youngest child was ten months old, the other two were one year, and four years, respectively. When it was remembered how the families of these children were crowded together, it would readily be understood how great was the chance for infection. The disease was quite difficult to treat, because of the smallness of the urethra. One troublesome feature was that the external parts became eczematous, owing to the accumulation of the discharges; and this was apt to lead to stricture of the meatus.

Dr. T. H. Manley reported a remarkable and unique case of ectopic pregnancy, presenting specimens, and introducing the patient from whom these had been removed. He said he had been called to see this woman after she had been under the care of two other physicians. The clinical indications were those of septic invasion resulting from peritonitis. In the region of the iliac fossa on one side there was a protrusion, which on palpation suggested the presence of pus. The history elicited was, that for about four months the patient had considered herself pregnant and had noticed nothing abnormal to this condition. She had, however, recently fallen over some loose planks left by builders on a sidewalk. Quickly supervening upon this accident had come a train of symptoms which had culminated in the condition in which the patient was found by Dr. Manley. There was high temperature, rapid and feeble pulse, tympanitis and suppression of urine, stoppage of bowel action and great prostration. Laparotomy seemed the only thing to do, and even this the operator had undertaken most unwillingly. On cutting down over the protrusion—instead of pus, blood clots were found. On these being cleared away, a fetus was discovered, but no placenta. Following the cord, it was found that this stretched across to the opposite side, and that there was the placenta. The fetus and secundines being removed, the cavity was flushed with warm water and drainage established through Douglas's *cul de sac*. The patient made an uneventful recovery and was now presented in fair health, and but little disfigured by the resulting cicatrix. Dr. Manley thought that this was the only case recorded of rupture of a previously unrecognized ectopic pregnancy by a traumatism.

Dr. J. Lewis Smith read a paper in the Pediatric section on peritonitis in infancy and childhood. Peritonitis, he said, was likely to occur at any age, but the most interesting and fatal form was that which occurred in the newly born. In this form there was no doubt that microbes played an important part in the etiology; the septic matter entering the system through the umbilicus, usually from the use of foul dressings, foul fingers, and so forth. Umbilical inflammation, with perhaps ulceration, and the formation of a phlegmon might occur and septic matter be taken up by the umbilical lymphatics or blood-vessels, and carried into the system. Peritonitis occurred in infancy and childhood from a variety of causes, such as extension of inflammation from the abdominal walls, or of the viscera, septic infection, chronic degenerative disease of the kidney, and cheesy degeneration of the mesenteric glands, which sometimes gave rise to inflammation in the portion of the peritoneum covering them. It was now known that a considerable number of diseases which were formerly supposed to be due to taking cold were caused by microbes. There was too great a tendency at the present time to ignore thermal changes in the atmosphere, or exposure to cold as a cause of disease. Intussusception and appendicitis was an occasional cause of peritonitis. It also often followed trauma of the abdomen. Children less frequently than adults had ulceration of Peyer's patches in typhoid fever, but it sometimes occurred, ending in perforation or rupture and fatal peritonitis. Quite a number of cases had recently been reported showing the microbic origin of peritonitis in certain instances. Some of the cases were affected by accidental inoculation, and others were due to inhalation of sewer gas. Experimentation had proven that to produce purulent peritonitis, it was necessary to exhibit pus-producing organisms, and irritants and non-pathogenic germs did not produce peritonitis, even in ever so small degree. Tubercular peritonitis was much more frequent in infancy and childhood than in adult life. The symptoms were more or less characteristic, and only when co-existing with some other disease was there any difficulty in making a diagnosis. Tenderness on pressure, pain, temperature, and position of the patient were the symptoms usually looked for in peritonitis. There was generally gaseous distention of the intestines, sometimes so great as to carry the apex of the heart upward. The liver and spleen were also pressed upward and backward. The displacement of these organs allowed the distended colon or portions of the duodenum or jejunum to lie in front of them, thereby changing the normal dull note on percussion for that of tympanitic resonance. Constipation was usually present in the early stage. Vomiting was a common and painful symptom. The pulse was accelerated, frequent and small. The countenance was anxious, but the mind was clear, or there might be mild delirium, with incoherency of speech. Retention of

urine was common. The relative proportion of the different inflammatory products varied greatly in different cases, and in all, not only were serum and fibrin present, but pus corpuscles could be detected under the microscope. The fibrinous exudation upon the peritoneal surface occurred either in patches, or continuously over a considerable part of the visceral peritoneum. It was prone to form a covering of various thicknesses over the large and immovable organs. Adhesions frequently took place between the intestines and viscera, producing disastrous results. Peritonitis in children was always a grave disease, in most instances its progress was towards a fatal termination. Prophylaxis and removal of the cause, Dr. Smith said, was probably the best way to deal with these cases.

Dr. Vaughan has recently had a case of fracture of the clavicle in that rare locality, near the sternal end. A very good result was obtained from pressure by means of pads and strips of adhesive plaster.

A convenient way of putting on the plaster-of-Paris jacket in paralytic cases has recently been described by Dr. John Woodbury when presenting a patient who had sustained fracture in the dorsal region, operated upon for cord pressure by Dr. McBurney. He folds a strip of cheese cloth so as to make a hammock about twenty feet long, four thicknesses, swung so that it can be tightened to any required degree. On this the child is laid, belly down, slits are cut to pass the hands and legs through, also one for the face. Two assistants now lift the hands and legs, the required degree of extension is made, and the plaster-of-Paris is applied over a knit shirt and around the hammock. The ends of the hammock are cut off when the jacket hardens. In the case operated upon by Dr. McBurney, thickened laminæ and spinous processes were removed, the dura being found normal was not opened, paralysis gradually disappeared, control was gained over the bladder and rectum, and the little patient when presented was able to walk.

IODOFORM AS A SUBSTITUTE FOR LUGOL'S SOLUTION.

Ernest Besnier prescribes iodoform for scrofulous infants, in the following formula:

℞ Iodoformi . . . . . gr. iss
Mellis . . . . . f℥iv
M. Sig. Dessertspoonful at a dose.

PERISCOPE.

Counter-Extension at the Knee.

Dr. Henry Ling Taylor, of New York, read at the meeting of the American Orthopedic Association, Philadelphia, September 16, 1890, a paper describing a good method of securing counter-extension at the knee-joint. As reported in the *Boston Medical and Surgical Journal*, October 16, 1890, he said:

"The patient being put to bed, the first step in the dressing is the application of adhesive plasters to each side of the leg and thigh. To get a firm and even grasp of the limb, we use a three-tailed or five-tailed plaster made as follows: four pieces of yellow adhesive plaster, about an inch and a half wide and eight inches long for an adult, having firmly sewed to one end a piece of webbing six inches long, and two strips of rubber plaster three-quarters of an inch wide and about twenty inches long, in such a manner that the webbing prolongs the yellow plaster, while the strips of rubber plaster make with it an angle of sixty degrees, as seen in the cut. We now have four three-tailed plasters with webbing attached. Two of these are applied to the leg below the knee, one to each side, the webbing starting about four inches above the ankle and falling towards it; the narrow strips of rubber plaster are wound spirally around the leg, slanting towards the knee. The two remaining three-tailed plasters are similarly applied to the thigh, the webbing starting a few inches below the level of the crotch and falling towards the pelvis. When in place, the plaster is retained by a light bandage; it is thus seen that when the four ends of the webbing are doubled on themselves and buckled over the edge of some form of fixation splint, reaching beyond the plaster in both directions, traction is exerted upon the knee both above and below.

"It is necessary to apply the plasters to the leg and fasten the webbing to the splint in such a manner that no prying or twisting force falls upon the knee, or pressure will be increased instead of relieved. The splint must be rigid to provide fixed points for the traction, and must immobolize the knee laterally and antero-posteriorly, without pressing upon the joint. If flexion is moderate, two straight strips of wood like laths or window-shade sticks, cut the proper length and provided with buckles near each end, will

do very well. The strips are well padded with cotton or folds of fabric above and below the knee and at the ends and securely fastened in place each side of the limb by bandaging them together over the top of the thigh, behind the knee and above the ankle; after this additional bandages may secure the whole. We now have to draw the pieces of webbing over the ends of the side splints as tightly as we wish, and fasten them into the buckles provided. Our simple counter-extension splint is now complete, but it is usually desirable to attach five or six pounds to the lower end of the apparatus by the ordinary cord, pulley and stirrup arrangement, the knee being carefully propped and supported in the flexed position by hard cushions or in a sling. If much flexion is present, a tracing of the leg should be taken on paper, and wooden side-splints with a corresponding angle and perhaps hollowed at the knee, can be prepared by the carpenter. This dressing has worked well and given prompt relief in a number of cases, but it occurred to me last summer that the ordinary plaster-of-Paris splint, reaching from above the ankle to near the crotch, might be utilized for the same purpose and prove more convenient in an ambulatory case. I have used such an arrangement with satisfaction in a number of cases, of which one was a bad old case of osteitis of the knee, with nearly ninety degrees of flexion, for whom I was preparing and have since applied, a more perfect steel splint. The plasters were applied to the limb as before, bandaged in place and the knee covered with cotton; over this was placed a light plaster-of-Paris splint with strong edges, over which small pieces of card-board were bent where the webbing was reflected. Buckles attached to bits of webbing were bandaged into the plaster on the outer and inner side of the limb at each end, and to these the plaster webbing was fastened.

"If the patient is small a stiff tin or zinc posterior splint could be bent to correspond to the angle of flexion, and turned up at the sides for lateral support and to receive the buckles near the ends. Whatever the form of apparatus we use for fixation and as a fixed point for our counter-traction, we must be careful, let me repeat, that no leverage, especially no prying or twisting force, is exerted upon the joint. If the counter-traction acts in the lines of the deformity, we should in most cases speedily get relief from pain, diminution of tenderness, heat and swelling, relaxation of the flexor muscles and an improved general condition of the patient. As the mechanical conditions are favorable, the amount of traction need not be great, not nearly so great as is required at the hip, but it should be constant, definite and in the proper direction. Even in our steel splints ratchet-traction is not required, as merely drawing the straps into the buckles by the hand gives a sufficient pull. After a few days or weeks motion will be freer; as the muscles relax the splint is straightened and counter-extension in the improved position continued. The later stages towards recovery may present indications for different management, and the ultimate result will depend upon an exact apprehension of the physiological requirements of the joint at each stage and precision in meeting their demands."

Autopsies in America.

The *Boston Medical and Surgical Journal*, November 6, 1890, says editorially:

Most American physicians realize the great advantages for promoting the advancement of knowledge which the medical profession of the continent of Europe have in comparison with us, in being able to procure and report a large number of autopsies. The report of a fatal case is not complete, and the statistics of a fatal disease are comparatively worthless without the certain knowledge which only an autopsy can give.

The fault, of course, lies in our laws, and the law is, undoubtedly, the expression of the will of the laity, and cannot be altered without a change in public opinion; but is not the medical profession also partly to blame? Is not the repugnance which is felt to autopsies in the community due largely to their infrequency? In countries where *post-mortems* are considered almost as much a necessary part of death as the services of the undertaker, very little opposition is met with, even from the less intelligent part of the community. In some European States all bodies are removed to a dead-house within twenty-four hours of death, where the diagnosis of death is confirmed, and an autopsy done. In at least one city a law exists that if any person objects to an examination, a complete autopsy must be made.

The American physician is often indifferent or careless after his patient is dead. Ex-

cept in large cities, it is difficult to undertake a *post-mortem* examination, and even where it would be comparatively easy, a busy doctor will often prefer to remain in doubt rather than undertake a disagreeable extra amount of work, and perhaps at the same time run the risk of offending the bereaved family. But every *post-mortem* that is made is so much aid in moulding public opinion, and it seems more than likely that if the medical profession as a whole should systematically request an examination whenever possible, the feeling in the community would soon change. Great assistance might be given in cities by a system which would make the details easy and inexpensive.

We already have laws demanding an autopsy in cases of suspicious death. Would it be too much too ask to have a law allowing a *post-mortem* on all patients who die in public institutions? This would be a great gain, for these cases have, as a rule, good *ante-mortem* clinical histories, and the autopsy can be held under the most favorable circumstances. The principal objections to such a law at present are, (1) a rare and indefinite semi-religious feeling connected with the resurrection of the body, in the presence of which feeling no one would want to enforce such a law; (2) the common feeling, already mentioned, of repugnance to the mutilation of the body of a relative, which is now the main stumbling-block; and (3) the fear in the public mind of *ante-mortem* autopsies. But the physician realizes that the signs of death are better understood by the pathologist than by the undertaker, and the danger of a premature autopsy is much less than the danger which now exists of premature embalming, nor is the mutilation of the body materially greater. The idea which we occasionally meet among the lower classes that the officers of a hospital take a fiendish delight in dissecting dead bodies, and rather desire the death of a patient in order to get a chance, might at first keep a few cases from going to institutions, but it probably would not do so for any length of time.

It is not necessary to discuss at length the advantages to the medical profession and to the laity of frequent autopsies, or their influence on insurance and mortality statistics and on quackery. Let us hope that before long not only will the physician know that the death certificate which he signs is absolutely true, but that the laity will prefer to know of what diseases their relatives die.

Mode of Action of Rennin and Fibrin-Ferment.

Drs. A. Sheridan Lea and W. Lee Dickinson send notes on this subject to the July number of the *Journal of Physiology*. Fick has recently put forward the view that the molecules of the clotting ferment do not require to come into intimate relationship with the molecules of the substance which is undergoing the change, but that when once the change has been set up by the ferment in any one portion of the substance, this change is propagated from particle to particle of the same without the further necessary intervention of the ferment. Their observations, on the contrary, go to prove that the mode of action of rennin and fibrin-ferment is essentially similar to that of other well characterized enzymes, as far as contact between the ferment and the alterable substance is concerned. — *Glasgow Medical Journal*, October, 1890.

Balantidium Coli.

Dr. L. A. Labrovska states in the *Bolnitchnaya Gazeta Botkina*, April 14 and 23, 1890, that cases of chronic catarrhal condition of the large intestine with presence of balantidii coli are seldom mentioned, and that from the small number of such cases which have been treated it has not yet been found how to kill the parasite rapidly. It has been found, however, that the chronic catarrhal condition of the intestine and the diarrhœa are relieved by directly destroying the parasite.

Labrovska enumerates the cases reported in literature, and in all cases apparently the results of treatment was very unsatisfactory. The patient either continued to suffer from chronic diarrhœa, or died. The *post mortem* usually showed ulceration of the lower bowel. In all cases the parasite was found during life, and especially when diarrhœa was marked. The author cites his own patient, a woman 70 years old, whose case was investigated carefully, the stools were often examined for parasites, and the effects of the drugs administered was watched during a period of several months. The patient had had seven relapses of chronic diarrhœa, with reappearance of the parasites in the stools. Of all the drugs used the best agents were, salol, 15 grains internally three times a day, and a 1 : 1,000 solution of sali-

cylic acid by enema once or twice a day. Salol was given to have salicylic acid formed in the lower bowel, as this acid is a germicide. After this is used the number of parasites decrease considerably.

The relapses of diarrhœa after a period of two, three or four weeks, during which no parasites were detected, is explained by the probable fact that the parasites remained in the intestine in an undeveloped form during that time. At the time of mature development of the parasite gastric irritation is re-established. It is stated also that the undeveloped parasite resists more vigorous germicidal solutions.

Very large blood corpuscles, three times the normal, are also found in the stools.

The parasite is known to live in the intestine of pigs; but in the author's and other cases the mode of infection could not be discovered.

Treatment of Diabetes Mellitus.

In a paper read before the International Medical Congress at Berlin Dr. Pavy (*Montreal Medical Journal*, October, 1890), said that the first consideration in the treatment is to control by dietetic measures the passage of sugar through the system. The real point, however, to be aimed at is to restore the assimilative power over the carbohydrate elements of food, and until this has been accomplished it cannot be said that a cure has been effected, but only that the disease is held in subjection and prevented, as long as the condition can be maintained, from leading on to an unfavorable issue. What most conduces to this desired restoration of assimilative power is the maintenance of a normal state of the system by keeping it free from the passage of sugar through it, and in this way bringing a healthy condition of body to bear in helping to promote a removal of the faulty state. According to his experience, opium and its derivatives codeine and morphine are the medicinal agents which, more than any others, assist in the actual cure of the disease, by which he means a restoration of the assimilative power which has been impaired.

The influence of these agents may be witnessed in cases where the sugar has been brought down by diet to a certain point, but is unsusceptible of entire removal from the system by dietetic treatment alone. The complete removal may then sometimes be observed to follow the subsequent administration of the drug, showing that the medicinal agent has acted in the direction of exerting a restraining influence over the abnormal production and elimination of sugar.

When cases of a favorable nature—that is, cases occurring above the middle period of life—are treated by these combined measures, and the treatment is steadily carried on for some time, it is a matter of common observation that the system of the patient becomes able to tolerate a certain amount of carbohydrate food, without its leading to the elimination of sugar. Often, with strict observance of the required treatment, the assimilative power is found to become so far re-established that a fair amount of the carbohydrate principles, or even an ordinary diet, may be taken without leading to the elimination of sugar. When this is the case, carbohydrate principles, according to the extent found to be tolerated, may be taken without occasioning harm; but the object is to keep below the point at which the escape of sugar takes place, and when this is done, actual benefit, instead of injury, is derived therefrom.

Dr. Pavy refers to the aid afforded by the quantitative testing of the urine. It is absolutely essential, he considers, in the management of a case, to possess the knowledge thus supplied, not only for the purpose of regulating the treatment according to the progress made, but also for keeping a check upon the manner in which the directions given are carried out. When in a case it is found to happen that the assimilative power has been restored, it is permissible to consider that an actual cure has been effected; but it is always requisite to bear in mind that a weak point has existed, and that it is advisable to avoid unduly taxing a power which has previously given evidence of being at fault.

Russian Institute of Bacteriology.

It is announced that a Pasteur Institute is to be established at St. Petersburg through the generosity of Prince Peter Oldenburg. The building, on Apothecary Island, is nearly completed, and will be known as the Institute of Experimental Medicine. The conduct of the studies in regard to rabies and contagious diseases generally will be intrusted to specialists in bacteriology, chemistry, biology and veterinary science.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

IN MEMORIAM.—SAMUEL LEWIS, M. D.

The death of Dr. Samuel Lewis, of Philadelphia, removes from the medical profession in this city one of its most interesting and honored members. The outlines of his professional career will be found in another part of this number of the REPORTER; but here the Editor would pay a short tribute to the personal character of one whose friendship was a treasure and whose approval was both reward and incentive. Only those who knew Dr. Lewis personally could fully appreciate the strength and charm of his character. He was a man of unswerving integrity—a clean, straight, honest man; a man of excellent judgment; and withal a man of such kind and gentle heart that all must love him. His influence was always good, and it was safe to submit any question of personal or professional morals or ethics to the touchstone of his action; for, in matters affecting individuals or the whole profession of the country, his course was sure to be that which eventually seemed the best and wisest.

The loss of such a man is a very great loss; for he was of the kind which keep the profession from yielding too much to the excitement and strain which our time puts on all classes of men. To him older men could look with confidence that he would maintain the best traditions of the profession, and young men could look as an example of what is really best in personal and professional character. May those who are like him be preserved and multiplied!

USE OF CHLORAL IN SURGERY.

Chloral was invented in 1832 by Liebig, but it was nearly forty years later, in 1871, before it was introduced to medicine by Liebreich. Since that time it has been used extensively and its physiological action has been determined very satisfactorily. Its most characteristic effects are upon the heart and circulation, and upon the nervous system. It depresses the heart and is capable of paralyzing the vaso-motor centre; it acts upon the cerebrum directly, producing sleep, and as a depressant upon the spinal cord and medulla, finally paralyzing the respiratory centre. Locally it acts as an irritant. Its physiological actions indicate sufficiently its therapeutic usefulness for medicinal purposes. The local use of chloral, however, in certain surgical affections has not excited very wide attention. Even Germain Sée, who does full justice to its physiological actions and medicinal uses, in an article published in *La Médecine Moderne*, July 3, 1890, says almost nothing of its local uses. Marc Sée supplies what is lacking in this respect, in the issue of the same journal for July 17. The latter says he began using chloral locally in 1865, his first case being one of ulcer of the foot

which was covered with psuedo-membranous and gangrenous exudate. The result was highly satisfactory, so that he came to use it largely, only abandoning it when attracted to carbolic acid by the claims made for it by Lister. Chloral is applied to the wounds by Marc Sée in weak solution. He regards it as a powerful antiseptic, which cleanses wounds rapidly and is without the inconveniences of alcohol. It is also hemostatic, immediately arresting the bloody oozing which often embarrasses a surgeon. In strong solution—equal parts chloral and water—it acts as a caustic; Sée has found a two or three per cent. solution the appropriate one for ordinary purposes.

In addition to wounds and ulcers, Sée has employed chloral with benefit as an injection into the urethra, vagina and bladder, in cases of catarrhal inflammation, and into fistulous tracks, and in deep suppurating cavities, when evacuation of the pus was poor in spite of drains. The coagulating power of chloral has been utilized in injections for the cure of hydrocele, as a substitute for iodine. Sée declares that he has employed chloral for this purpose in ten per cent. solution, for the past fifteen years. He has treated perhaps two hundred cases, and asserts that all have been cured without the least accident, and that he has no knowledge of a single relapse. His method consists in injecting thirty grams of the solution, which is allowed to remain in for fifteen minutes and then withdrawn partly or wholly. In two or three days a more or less considerable effusion into the tunica vaginalis takes place, but this is absorbed gradually and completely. Such chloral injections are not suitable for all cases, because no injections will cure a case in which the walls of the sac have become hard and rigid; incision alone suffices here.

In the treatment of varicose veins, Sée has followed the method of Schwalbe, but has substituted chloral for alcohol. The result has been the same, the blood has been coagulated slowly in the vessels, which subsequently retract slowly. He has also made trial of it by injection into cysts of various kinds, but the results are as yet incomplete.

The writer cannot verify most of the assertions of Sée, but he has found chloral valuable in a class of painful irritable ulcers which Sée does not specifically mention, namely fissures of the anus. The employment of five grains of chloral in rectal suppository, repeated two or three times a day, and after a movement of the bowels, has cured such an ulcer without resort to the knife. Chloral, employed in the same way, has also proved very soothing and healing in slight lacerations of the vaginal mucous membrane. If Marc Sée's experiences with it is verified by others, chloral will have a much more extended use, becoming a substitute for some of the established uses of the tincture of iodine. We hope some one nearer home will supply the needed information for confirming or refuting his observations.

TUBERCULOSIS AND PSEUDO-TUBERCULOSIS.

Tuberculosis has been a scourge of the human race for centuries. As physical diagnosis was practically unknown until the time of Laënnec, and even pathological anatomy had not begun to be studied until towards the close of the sixteenth century, it is easy to see how many wasting diseases, being judged by their symptoms only, were confounded with tuberculosis. But even after pathological anatomy became a general study, much confusion existed as to what constituted tubercle and what did not. At one time, and that as late as the first half of the present century, some held that granulations were the only true tubercles, while others maintained that caseous masses were the true type, and that miliary tuberculosis was a special disease; and still others that they were all different manifestations of the same disease.

G. H. Roger, in the *Gazette Hebdoma-*

daire, November 8, 1890, gives an excellent review of the past and present views of tuberculosis and its pathology, about which we have admittedly learned much, but have certainly much more to learn. He points out that the anatomical arrangement believed to be characteristic of tubercle—*i. e.*, three concentric zones: in the centre a giant cell, around it epitheloid cells, and surrounding all and forming the periphery, a ring of embryonal elements—is met with in other diseases, especially in syphilitic products, and has been seen to follow the introduction into the organism of animal parasites and inert foreign bodies. This arrangement, therefore, indicates nothing in itself; it is only the reaction of the organism in the presence of a pathogenic agent. Histology availed nothing to distinguish true tubercle from false, because it was not a question of structure; but when Villemin, in 1866, showed that tubercle was inoculable, and that by inoculation tuberculosis could be transmitted, the discovery afforded the desired means of differential tuberculosis. It was found that true tubercle when inoculated produced a similar lesion in the second animal, and that the disease by successive inoculations could be transmitted to a third animal, and from the third to a fourth, and so on for a series; whereas false tubercle could at most produce in an animal only a nodule from irritation, from which nothing further could be obtained. The macroscopic and even microscopic appearances of the two tubercles were the same, but one had infective properties and the other had not.

Another form of pseudo-tubercle is produced by various worms, which have been described by Leuckart, Koch and Laulaizé These produce by irritation a tubercle, but it is not infective. Such a tubercle, produced by the eggs of a distoma, has been found in a man who died of beri-beri.

When Koch, in 1882, described the tubercle bacillus, the specific character of tuberculosis became, in Roger's opinion, incontestable. At once the unity of the various tubercular manifestations—certain pleurisies, cold abscesses, white swellings and Potts' disease—seemed assured. Very soon, however, Malassez and Vignal described a tuberculosis due to another parasite than that of Koch. By inoculating a cutaneous tubercle, these experimenters demonstrated a disease transmissible in series, and seemingly produced by a mass of zoöglœa. Their results have been confirmed by other observers. Subsequently, Roger published, in company with Charrin, a note of a case of tuberculosis which arose spontaneously in a guinea-pig. The parasite producing it was cultivated, and pure cultures reproduced the disease in the rabbit, guinea-pig, and at times in the white mouse. The bacillus was different from that of Koch's; it produced granulations without degeneration, and the nodules stained differently from those of the zoöglœic tuberculosis. Other forms of tuberculosis have been described by Courmont, Pflüg, Nocard and Eppinger.

The tuberculoses produced by pathogenic agents other than the bacillus of Koch, are by Roger united under the name pseudo-tuberculosis. From this it would appear that tubercle can no longer be regarded as the specific product of the tubercle bacillus of Koch, but it seems to be a reaction of the organism which can be excited by very diverse agents. It should not be forgotten, however, that, with the exception of the disease produced by Malassez and Vignal by the inoculation of a human cutaneous tubercle, the pseudo-tuberculoses of microbic origin are observed only in animals. It is for the pathology of the future to determine the relation that exists between tuberculosis in animals and that in man; in the meantime we have at least learned that mere anatomical structure indicates nothing as regards the cause of the tubercle, and that there are different kinds even of infective tubercle, due either to different causes altogether or to different species of the same cause.

KOCH'S "LYMPH."

A letter received just as we go to press, from the regular correspondent of the MEDICAL AND SURGICAL REPORTER in Berlin, in reply to instructions cabled to him, says: "At present no lymph at all is to be had for any one, not even the large clinics in the Empire. As soon as obtainable you will get some."

We believe that this is about as near as any American has come to getting any of this remedy, unless Dr. Jacobi has really had some. When we get nearer and can inform the readers of the REPORTER more fully about it and the effect of its administration in this country, we shall hasten to do so.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

PRACTICAL DIAGNOSIS AND PRACTICAL URINALYSIS. An Epitome of the Physical Signs of the Heart, Lung, Liver, Kidney and Spleen in Health and Disease. Edited by JOHN E. CLARK, M. D., Professor of General Chemistry and Physics in the Detroit College of Medicine. Fully illustrated. 12mo, pp. 193. Detroit: The Illustrated Medical Journal Co., 1890. Price, $1.00.

Dr. Clark states in his introduction that there is a demand for a work on physicial diagnosis which gives the main points briefly and plainly. He disclaims originality for the present book, except so far as the arrangement is concerned, and for some annotations and additions. The chapters on Urinalysis, however, are his own, being the laboratory processes used by him in instructing his classes in the chemical laboratory at the Detroit College of Medicine.

The book is full of useful information in a condensed form. It could, however, be improved in certain respects. For instance, in mentioning the physical signs of the first stage of phthisis, Dr. Clark says, under auscultation: "*At commencement*, jerky, 'wavy' inspiration; *at end*, inspiration harsh, and expiration prolonged, becoming 'tubular.'" This is too brief to be clear, and 'tubular' is open to misapprehension.

The book as a whole is a good one, its defects being such as are almost inevitable results of great condensation.

—Adulterated mace has appeared in Germany. The adulterant, according to Hanausek, is another species of myristica, probably Myristica malabarica, or Bombay mace.

CORRESPONDENCE.

Consumption Among Firemen.

TO THE EDITOR.

Sir: In your issue of November 29, Dr. J. H. Musser criticises my paper on *Consumption Among Firemen*, which appeared in the REPORTER, September 27, 1890. He states that I was either imposed on by the sources of my information, or misapprehend the facts on which my paper is based. I do not claim infallibility for myself; but would assure him that my only motive in undertaking that work was not, as he intimates, my anxiety to pull down anything which has the least claim to be called scientific medicine, but to learn the truth of a problem in the evolution of a disease which had not before been investigated.

He goes over the same ground which I traversed last August, so far as the Philadelphia Fire Department is concerned, and makes the discovery that out of the 33 members who died, 13 were suffering with the disease before they entered the Department. I agree with him that, if this is true, a great part if not all of the force of my conclusions is destroyed. But is this true, or is it mere fiction? Common prudence ought to dictate that before an assertion of such serious import is made, it should be substantiated by at least the semblance of invincible testimony, but all that he knows, he states, is the declaration of the clerk of the Philadelphia Fire Department. On interviewing this gentleman since, in regard to this question, he stated to me that his belief that these men were consumptive when they entered the Department, rested on the fact that they died in a comparatively short time after admission; and that he had no medical evidence whatever to support this opinion. This is a very natural view for a non-medical mind to offer in explanation of the astonishing death-rate which occurs among these men from consumption; but a careful medical man, especially when criticising another, ought to be on his guard against citing lay reports as if they were medical facts. Is this the way in which he and his *confrères* "add new facts and build up the science of medicine"? Is this befitting to one who says that he is "impatient with the lax processes of reasoning employed" by others? A visit to the Department of Public Safety, Broad and Market streets, would have shown Dr. Musser that, although the service had

an examining surgeon only during the last five or six years, the Department had been earnestly striving to admit none but able-bodied men for the last seventeen years, and even longer; that the applicant was required to make oath that he is free from disease; and that only after thorough scrutiny by the head of the Department was he admitted. Dr. Musser's assertion that these invalids were admitted on account of strong political influence is unsupported, and I trust he will be kind enough to furnish the proof on which it is founded.

That the high death-rate from consumption among the firemen of this city does not rest on any such fictitious basis as that which is assigned by Dr. Musser, is evident from the fact that a similar death-rate prevails among the firemen of other cities, the statistics of which I collected. *Fire and Water*, August 16, 1890, (a journal published in New York, and devoted to the interests of firemen) states "that the *average fire department* (Italics mine) draws its material principally from the ranks of active young mechanics, who bring to their new calling strength and energy. In New York the requirements are such as to guard about as effectually as is possible against the admission of poor material." Yet in New York City, and in spite of rigid medical examinations since 1867, more than 30 per cent. of the deaths among firemen were caused by consumption, and 10 per cent. more by other diseases of the lungs, as is shown in my paper.

Dr. Musser seems to be skeptical as to the assumption that firemen lead an out-door life. If these men could extinguish the fires of this city, undergo the most terrible hardships and risks to life and limb while pursuing their duty, without leaving their engine houses, their work might properly be called an in-door occupation: otherwise, I think not.

Now is the exaggerated death-rate of firemen from consumption due to the ravages of the tubercle bacilli, as Dr. Musser assumes, or to the influence of their peculiar employment? If the former, then it must be shown that they are more than ordinarily exposed to these organisms. Even if this were true, it would still have to be shown why physicians, nurses and attendants in consumption hospitals, who live, breathe, and have their being among these germs, are comparatively free from this disease, and why their death-rate from consumption, when compared with that of firemen, sinks into veritable insignificance. If the bacillus theory works in one case, it must also work in the other. To say that a fireman, suffering and dying from consumption, is a source of infection to his companions, is simply an unproven statement. There is probably not an adult in this city who has not at some time lived with a consumptive member of his family, or who has not occupied a house in which a consumptive lived or died, and yet the relative death-rate from consumption among firemen exceeds that of the general adult population by more than 25 per cent. Why is this, if there is not something in the fireman's vocation, independent of the suppositious danger of this germ, which makes him so liable to this disease?

I think that I have not overstated the death-rate from consumption among our city firemen; for since my paper has been published, I learned that, owing to a periodical examination and discharge of invalid members, not all the deaths occurring among those who served in the department are officially reported. But, in order to arrive at the exact truth in this matter, I cordially invite Dr. Musser to point out the other misapprehensions, spurious arguments and the quotation of worthless authorities, which he says are contained in my paper.

In conclusion I desire to say, however, that if this criticism is a specimen of "the close reasoning and absolute step-by-step demonstration" which is pursued by the adherents of the contagion theory, it is not at all surprising why their logic has betrayed them into an endorsement of some of the wildest medical vagaries of the present age.

Yours truly,

THOMAS J. MAYS, M. D.

Philadelphia.

Atmospheric Tractor.

TO THE EDITOR.

Sir: I have discovered within the last few days, that the "Atmospheric Tractor" described in the REPORTER, November 29, 1890, can be made to adhere firmly against the head of the child by the employment of only a few ounces of force. The method described last week consisted in displacing the air from the cup by a pressure proportionate to the area of the top of the handle or vacuum producer. If the diameter of the handle were one inch, the pressure required

would be about ten pounds. This would not, however, be exerted against the head, but entirely against the air within the cup.

By the new method of application, the sides of the cup are to be inverted, and the fundus placed firmly against the presenting part. If the sides of the cup be then gently reinverted, they will drive out the underlying air and become firmly affixed to the surface. Traction may then be performed in the usual manner. If the vacuum is not sufficiently perfect, as can be readily ascertained by touch, sufficient pressure may be afterwards exercised on the handle or vacuum producer to flatten the cup.

One of the chief advantages of the tractor is the facility with which it can be applied and removed. It can be applied in thirty seconds or less, and it can be removed in five seconds. To detach it, all that is necessary is to push up its edge. The air immediately rushes in beneath and separates it from the entire surface.

Another advantage is that it does not compress the head nor elongate any of its diameters, nor does its application or employment inflict pain, nor require to be preceded or accompanied by the administration of anæsthetics. It can be used long before the forceps would be available, and in all cases where their use would not be permissible.

Like all other mechanical devices, it must be used with "brains," in order to derive the greatest amount of benefit from it.

Unlike other obstetrical instruments, serious injury is not likely to result from its use by even the ignorant or reckless. Injurious pressure or force cannot be exerted with it. It weighs less than two ounces. Its sides are as soft and yielding as the surfaces with which it comes in contact. It cannot be affixed to a surface that is not continuous, resisting, and at least four and one-half square inches in area. It is, therefore, a mechanical impossibility for it to be applied over the eyes, mouth, nose or genital organs, even if those parts were so congested by pressure and detention as to render their recognition difficult.

Yours truly,

PETER MCCAHEY, M. D.
219 North Twenty-second St.

A NEW OPENING.—Carthage, the old city of Dido and Hannibal, is to be turned into a winter resort for invalids and pleasure-seekers.

NOTES AND COMMENTS.

Clinical Experiments with Diuretin.

Koritschoner has recently made numerous clinical trials at the Medical Clinic of Professor Schrôtter, of Vienna, with the new diuretic, *diuretin*, which is a mixture of sodium salicylate and theobromine. These experiments pertained to thirty-eight cases of general dropsy. Ten of these were cases of cardiac dropsy from chronic valvular disease; twelve were cases of dropsy from Bright's disease in some stage; in six the general anasarca was due to dilatation of the heart following emphysema or arterio-sclerosis; in four the cause of the dropsy was degeneration of the myocardium; in three it was hepatic cirrhosis; in two it was tuberculosis of the lung and serous membranes, and in one cancer of the liver.

The formula which Koritschoner uses is as follows:

℞ Salicylate of soda and theobromine, 4 to 8 grams
Warm water . . . . . 150 "

M. Dose, a tablespoonful every hour or every two hours.

Diuretin should be given in rather large doses; little benefit can be expected from a less quantity than four grams (sixty grains) a day; ordinarily to get the full advantage of the drug, medium doses, amounting to five or six, and maximum doses amounting to eight or ten grams, in the twenty-four hours, should be administered.

Diuretin is generally well supported, even when its use is prolonged for months. It rarely causes nausea, even in chronic Bright's disease when the appetite is gone, and but little food is tolerated. It does not cause vertigo; in rare instances patients complain of palpitation and temporary cardiac distress. Sometimes diuretin provokes diarrhœa.

As a result of these trials by the Vienna physician, the salicylate of soda and theobromine was found to be a very powerful diuretic, and in only five cases did it prove to be without action; these were cases of chronic Bright's disease, arterio-sclerosis with fatty myocardium, tuberculosis of the lungs and serous membranes—all had arrived at the last degree of cachexia, and succumbed a few days after their admission to the hospital. In ten other cases the action of the salt was much superior to that of

digitalis, acetate of potash and all other diuretics that had been administered, though but moderate benefit followed the administration of the remedy. In the majority of the patients (twenty-three out of thirty-eight), the effect obtained was excellent, the dropsical effusions rapidly disappeared, and general amelioration followed. There is even danger that under the influence of the abundant diuresis caused by the drug, the ascites and œdema may disappear so speedily as to cause dangerous collapse. On this account, Koritschoner urges that in cases of abundant effusions, the remedy should be given with considerable caution; he would, in fact, advise always to begin the treatment by a dosage of four grams a day, and if this quantity makes no sensible increase in the urine, it may be augmented by one gram a day till a sufficient result is obtained.

The diuretic action of this medicine is said to be more marked in cardiac dropsies than in renal or hepatic, yet it may render precious service in chronic Bright's disease. In fact, in this disease where all the ordinary diuretics are apt to fail, the quantity of urine excreted often becomes augmented five or six times under the influence of the salicylate of soda and theobromine. In some cases of Bright's disease, the remedy seems to exert its principal action on the intestines, producing an abundant serous diarrhœa, which in a very short time causes the œdema to disappear, without too great enfeeblement of the patient.

According to the researches of Schrœder and Gram, the diuretic effect of the salicylate of soda and theobromine is due to the excitant action of the drug on the renal epithelium. As the epithelium is the principal seat of lesion in chronic parenchymatous nephritis, it might be feared that diuretin would be injurious in Bright's disease. The observations of Koritschoner show that this fear is not well founded, and that diuretin excites the renal functions without irritating the kidneys. Thus, in two cases of acute scarlatinous nephritis when Koritschoner gave diuretin in large doses, the patient recovered with astonishing rapidity, and without any complications. Under the influence of the medicament, the blood corpuscles and hyaline casts were seen from day to day to disappear from the urine. This same favorable action of diuretin on the nephritic processes has also been noted in chronic Bright's disease.

The new drug has not as yet—as far as we have been able to ascertain—been much introduced into this country, and as theobromine is very expensive, and as the cost of a drug is an important item in the economies of many physicians and their patients, it is doubtful whether many serious trials will be made with diuretin for some time to come.—*Boston Medical and Surgical Journal*, October 30, 1890.

Koch's Remedy for Consumption.

The *New York Medical Journal* says, in an editorial, November 22, 1890:

Koch's theory of the curative action of the remedy is, not that it kills the bacilli, but that it sets up in the diseased living tissue a process that ends in its necrosis; and he implies that the bacilli are cast off with the dead tissue, and that incompleteness of this part of the process may lead to re-infection, as also may failure of the dead tissue to become wholly separated from the organism.

To support all this, he gives absolutely no statistical evidence and not a single clinical history. We have only his statements, which in some respects are rather vague. We may add that so astounding are these statements —so utterly at variance with any known biological laws—that nothing but Koch's great name and the prevalent confidence in his accuracy, produced by his past successes, would lead one to consider his article at all seriously. He states positively that patients in the first stage of phthisis were freed from every symptom of disease, and might be pronounced cured; that patients with cavities not yet too highly developed improved considerably, and were almost cured; but that in very advanced cases there was no improvement. He says that by this he is led to suppose that phthisis, in the beginning, can be cured with certainty by his remedy, but he admits that, thus far, no conclusive experience can be brought forward to prove that the cure is lasting.

In regard to his theory of the way in which the remedy acts, namely, that it destroys tubercular tissue without affecting any other structure, whether healthy or diseased, it must be said that he professes to have discovered a substance that has this extraordinary peculiarity—it is destructive to the cells concerned in the inflammation called tubercular. Possibly it may kill them directly because it is poisonous to cells engaged in the formation of tubercle, or it

may kill them indirectly by producing inflammatory changes about them, or it may destroy them in some other manner. Whatever may be the way in which it acts, the statement is positive that it is an enemy of tubercular processes, not of tubercle bacilli. Indeed the bacilli in the dead tissue may again infect the organism, and probably surgical interference will be needed to remove them. No substance is known that has an effect at all comparable to what is alleged for this remedy. Vaccination, of course, is by no means analogous in its action, since a living organism is introduced which does not destroy the small-pox poison, but only renders the body proof against it, and, moreover, does not, so far as we know, seek out particular cells or tissues for destruction.

Acute Dementia Treated by Heat and Electricity.

At a recent meeting of the Glasgow Pathological and Clinical Society Dr. Alexander Robertson showed a patient who had recovered from this form of mental disease. She was 20 years old, and had been admitted to the Infirmary on January 10, 1890. She was of a retiring disposition when well, and very much given to reading when free from work. Menstruation had been regular up to the time of her illness. This was of about two months' standing, and no definite cause was known. There was no tendency to insanity in the family. There was some excitement with hallucinations at the beginning of the disorder, but after a few days she had passed into a state of much mental degradation. She was of filthy habits, and required to be fed by a nurse. She was quite passive in every respect. There was marked emaciation; her heart's action was very weak, with a very feeble pulse, and there was coldness and blueness of the extremities. Temperature was generally 1° F., subnormal. Her tongue was coated, and there were sores about the mouth.

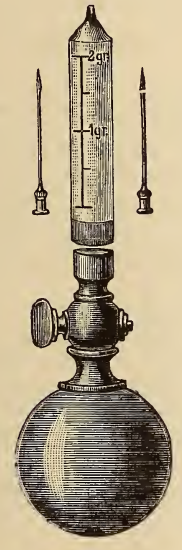
The account of the case in the *Glasgow Medical Journal*, October, 1890, states that the treatment was, in the first instance, directed to stimulation and support of the general system. Fluid food and brandy were administered at short intervals night and day. Care was taken to keep the bowels free, both with stimulating enemata and laxatives by the mouth. She improved a little under this treatment, but this improvement was so slight that the propriety of sending her to a lunatic asylum was carefully considered about three weeks after her admission. It was, however, determined to try the effect of direct stimulating applications to the brain. So, on February 1, heat was ordered to be applied to the head by the water-cap for an hour daily, at 110° Fahr. This was continued for about a fortnight, and then the temperature of the water was gradually reduced during the second half of the hour until only ice-water was circulated; and this was continued for twenty minutes. On February 20 there was distinct improvement; the patient took her food herself and showed more mental activity in other respects. From an early stage of the treatment, friction to the surface was employed, but now systematic massage for three-quarters of an hour morning and evening was commenced, the heat and cold to the head being discontinued. After three weeks of the treatment by massage she had further improved in every way; but even then she had not become quite correct in her habits. At this time she gave slow and correct answers to two or three simple questions—such as telling her name and residence. The massage was now stopped and the continuous current to the head was begun and continued during the next month until April 21. The application was made every second day, and the strength of the current was four milliampères, but only two for the first two days. The positive pole was applied to the lower part of the spine, and the negative was slowly moved over the head. In about a fortnight the patient had become perfectly correct in her habits, was talking intelligently, and assisting in the maid-work. Her mind, however, seemed a little slow, though this appearance might be due to her natural diffidence. She had gained in weight.

Dr. Robertson said that there was no distinct improvement under general stimulation of the system, and this did not clearly begin till after the local applications to the head. The case, he said—so far as treatment and its results were concerned—corresponded with one of catalepsy which had been shown to the Medico-Chirurgical Society some years ago. Heat and cold, followed by electricity, had been used in that case. Dr. Robertson also said there was a special interest in the treatment of a patient with mental disease in a general hospital at present, owing to the late discussion in the

London County Council on the projected hospital for the treatment of acute insanity in London.

Koch's Syringe.

The readers of the REPORTER, who have been reading about the method of treating phthisis and lupus proposed by Koch, have remarked that he speaks of employing a hypodermic syringe of peculiar construction. This syringe—of which a cut has been sent to the REPORTER by the maker, E. Kraus, of Berlin—as will be seen by the accompanying illustration, consists of a



graduated glass cylinder, which holds about half a drachm, with a conical glass end, to which the needle is applied; and a rubber bulb with a silver tube to connect it with the glass cylinder.

This instrument is one which will no doubt be fully appreciated by the readers of the REPORTER who have read the articles of Dr. J. J. Thomas, of Youngstown, Ohio, in this journal, September 28, 1889, and October 25, 1890, because it is constructed on precisely the same principle as is the syringe Dr. Thomas uses, and as was proposed in 1876 by Dr. Edgar Holden, of Newark, N. J.

The syringe of Prof. Koch is an ingenious and very complete instrument, and seems to be admirably adapted to any sort of hypodermic injection.

Inebriety and Life Insurance.

The American Association for the Study and Cure of Inebriety will hold the first of a series of monthly meetings at the Hall of the New York Academy of Medicine, on Forty-third street, Dec. 10, at 8 P. M.

The subject of the evening will be presented by papers from Dr. T. D. Crothers, of Hartford, Conn., "On Alcoholic Inebriety and Life Insurance," and by Dr. J. B. Mattison, of Brooklyn, N. Y., "On Opium Addiction and Its Relation to Life Insurance." Other leading physicians will participate in the discussion.

Remedies for Skin Diseases.

The *British Journal of Dermatology*, November, 1890, contains the following valuable formulæ:

Aristol Solution in Ether.

℞ Aristol . . . . . 5 parts
Ether . . . . . 50 "

Aristol Collodion.

℞ Aristol . . . . . 2 parts
Collodion . . . . . 18 "

Aristol Pomade.

℞ Aristol . . . . . 5 parts
Vaseline . . . . . 15 "
Lanoline . . . . . 30 "

Strong Tincture of Iodine.—One of the best solvents of iodine is methylated spirits of wine. With this any strength of solution can be made in a very short time, which is a convenience when we wish to apply a powerful remedy to a very limited area.

Unna's Gelatine Dressing.

℞ Oxide of zinc and pure gelatine . each 10 parts
Glycerine and distilled water . . each 40 "

Atonic Ulcers.—Since the publication of an article on this substance, by Swetnam, in the *Canadian Practitioner*, in 1887, Necker, of the University of Toronto, has made frequent use of this drug in the treatment of ulcers and wounds, only employing it when the wounds seemed "atonic." After an experience extending over a few years he concludes that it is superior to iodoform and the majority of other dressings. Having powdered the surface over with the drug, he applies cotton-wool or antiseptic gauze, and, in addition, puts on a bandage to exert some degree of pressure. At the end of the third day the dressing is removed, the wound

cleaned with an aqueous solution of carbolic acid, and the dressing re-applied.

For Sycosis.

℞ Iodoform . . . . . 4 parts
Lanoline . . . . . 30 "

Leache recommends this ointment to be applied every night, and to be washed off in the morning with hot water.

For Warts.

℞ Corrosive sublimate . . . . . 1 part
Flexible collodion . . . . . 30 "

To be applied once daily upon the wart and around its base.

For Perspiring Hands.

℞ Eau de cologne . . . . . 120 parts
Tinct. of belladonna . . . . . 15 "

To be used as a lotion.

For Pediculi Pubis.—Brocq uses a lotion composed of

℞ Vinegar . . . . . 500 parts
Sublimate . . . . . 1 "

This application is said not only to kill the pediculi, but also to remove the nits.

For Eczema.

℞ Oleate of cocaine . . . . . 1–2 parts
Lanolin . . . . . 40 "
Olive oil . . . . . 10 "

This is recommended by Lustgarten for the treatment of eczema of the anus and genitals. Two applications daily, followed by the use of some absorbent dusting powder, hot hip-baths and soap. For the relief of pruritus ani he uses suppositories containing the oleate of cocaine.

For Intertrigo.—Wertheimer uses the following lotion for intertrigo, and speaks of the good effect often rapidly produced. He applies a compress wetted with the lotion and placed in contact with the part affected for an hour at a time, three or four times a day.

℞ Corrosive sublimate . . . . . 1 part
Distilled water . . . . . 2,000 "

If the intertrigo becomes very severe he prefers the local application of phenol, chloride of lime, etc., and also finds lotions containing alcohol or iodine very serviceable.

Saccharin Gun-Powder.

The *Druggists' Circular*, October, 1890, states that experiments were then being made with a view to the substitution of saccharin for sulphur and charcoal in the manufacture of gun-powder. The resulting compound is of a yellowish color, and when burned makes a good deal of smoke, but for mining purposes is equal to the common article.

Cocaine for Painful Teething.

The following prescription is taken from *Merck's Bulletin*, October, 1890.

℞ Cocaine hydrochlorate . . . . 1½ grs.
Syrup . . . . . 2 fl. drachms
Tincture of Coveus . . . . . 20 drops

M. Sig. To be rubbed on the gums several times a day.

OBITUARY.

SAMUEL LEWIS, M. D.

Dr. Samuel Lewis died, November 26, at Bryn Mawr, near Philadelphia. Dr. Lewis was born on the island of Barbadoes, West Indies, in 1813. He studied medicine in the University of Edinburgh, from which he was graduated in 1840 with the degree of M. D. In the same year he was elected a member of the Royal Medical and the Royal Physical Societies of Edinburgh, as well as a member of the Philadelphia College of Physicians. He was also elected to the membership of the American Medical Association in 1851, to the Philadelphia Academy of Sciences in 1855, and to the Pathological Society in 1860.

In 1884 Dr. Lewis was chosen President of the College of Physicians, but was obliged to resign a few months later on account of ill health. Dr. Lewis was an important contributor to medical and surgical literature, and it was due entirely to his generosity and enterprise that the Lewis Library was formed and united with the library of the College of Physicians of Philadelphia. The library, which contains an excellent portrait of its benefactor, numbers more than 10,000 volumes, some of which are extremely rare and of the very greatest value. During the last years of his life the perfecting of this library was the object of Dr. Lewis's unremitting care; and to his devotion, extraordinary judgment and faultless taste is due to a great degree the fact that the Library of the College of Physicians of Philadelphia has no equal in this country except the Library of the Government at Washington.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{50}$ gr.), Atropiæ Sulph. ($\frac{1}{500}$ gr.), Codeia ($\frac{1}{10}$ gr.), Antimony Tart. ($\frac{1}{15}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{50}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonials from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of the profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that the applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

Clinical Lectures.

POTT'S DISEASE OF THE SPINE.[1]

BY PROFESSOR V. P. GIBNEY, M. D.

The approach to the subject must necessarily be by way of definition, etiology, pathology, and early diagnosis. The term Pott's Disease of the Spine is sufficiently explicit, is sufficiently well known the world over, to make this name not only popular, but equal to all needs. Percival Pott, you will remember, a little over a hundred years ago, in describing the affection, described it so accurately that his name has remained to the present day. He wrote about that "kind of palsy" which accompanies this disease, and gave us a very fine clinical picture of the paralysis of compression myelitis. Certain authorities within the past few years have endeavored to substitute the name spondylitis, and have written and talked about spondylitis simply because *spondylos* means a vertebra and *itis* means inflammation. Long before the introduction of this name, neuologists were familiar with the term spondylitis, and knew the affection as one of rheumatoid periarthritis, affecting chiefly the spinous processes and lateral masses, the inflammation encroaching on the foramina of exit and producing various painful neuralgias. The baths of Europe have for years treated such cases, and Julius Brown in time past has described fully the affection as known to the neurologist. Pott's Disease is, therefore, not the spondylitis of medicine, but is what the Germans have preferred to call it, a spondyl-arthrocace, meaning a caseous degeneration of the body of the vertebræ, involving scarcely at all the lateral masses or spinous processes. It is true, as the disease progresses, these processes are secondarily involved, as the bodies give way and fall together. The term "angular curvature" is objectionable, because curves are not angular and angles are not curves. The kyphosis which results from this disease, is in contradistinction to lordosis—which belongs to lateral curvature of the spine—a deformity not dependent on any inflammatory lesion. The term "lordosis" is used also to indicate an incurvation of the spinal column, and the deformity is generally compensatory to a kyphosis. These terms—"kyphosis," "scoliosis" and "lordosis"—date back to the age of Hippocrates. The terms "tuberculosis of the spine," or "tubercular ostitis," would be more in accord with the pathology of the present day, but the introduction of any new names is confusing somewhat to the medical mind, and personally, I have no objection to adhering to the old name: "Pott's Disease of the Spine." If the term "tubercular" could be introduced, I should feel that a better appreciation of the lesion could be had, and the surgeon would then be forewarned; and to be forewarned is to be forearmed.

Pathology.—The lesion which produces the deformity now under discussion is an inflammatory focus in the body of a vertebra, at or near the centre or centres of development. It begins as a small reddish spot, gradually extending by continuity, very like the initial lesion of vaccination, encroaching upon the healthy tissue, changing this both in color and consistence, the centre gradually breaking down and becoming yellowish, finally leaving a cavity. The process is very slow. Exacerbations are caused by trauma, or strain, or exposure to cold. The exacerbation consists in a rapid extension of the inflammatory process to the periphery, involving the cartilages and joint structures generally, giving rise to a true arthritis. Painful symptoms then appear. We have the "girdle pain," the stooping pos-

[1] Delivered at the New York Polyclinic, November 22, 1890.

ture, sensitiveness to the slightest jar or concussion, the peculiar gait, short step, what is known as a spinal limp, care maintained both in sitting and standing and walking, an expression of pain. On the subsidence of the exacerbation, these symptoms grow less pronounced, the inflammatory area approximates its original size, but there is left a vulnerable area of tissue, and subsequent exacerbations finally succeed in breaking this down. Muscular spasm plays an important part in the disease and assists in the production of deformity, and finally an abscess forms, to remain incapsuled or to find its way to the surface. It not infrequently happens that incapsulation takes place, the tissues thereabout are thickened by the inflammatory process, and a patient may go through life with one of these caseous sacs left by absorption of the fluid contents.

Early Diagnosis. — The recognition of Pott's disease before the stage of deformity is the most important element in the management of the case. The clinical picture in substance is this: a moderate amount of irritability, this irritability showing itself by crying when the child is handled or lifted by the side; moaning during the sleep—not the scream that one gets in disease of the hip; a stiffness on rising in the morning; exceeding care in the gait; short steps; a disposition to lie across the mother's lap or on the floor, prone across a chair; pains in the epigastrium, especially if the disease be in the dorsal region; awkwardness in the position of the head, when the disease is in the upper dorsal or cervical; pains in the lower limbs, if the disease be in the lumbar region; a peculiar mode of rising from a chair or the floor, namely, climbing up on the knees, as it is called, the child holding the spine stiffly and raising itself by putting a hand on the knee and then climbing up the thigh until an erect posture is assumed. All these symptoms go to make up the clinical picture of a case of Pott's disease in the early stage.

The examination of a case at this stage will reveal a slight deviation of the spinal column to one side or the other; a rigidity of the latissimus dorsi or erector spinæ muscles; a shrugging of the shoulders; no angular projection; relief afforded by traction in the horizontal position, for instance. If you lay the child across your knees and gradually extend the column; then the child will take a long breath and express a sense of relief. While making this test, bring the limbs together again, and an expression of pain will be noted; if the suspected portion of the column be in the lower dorsal or lumbar region, a little reflex spasm of the psoas and iliacus muscles can be found by hyper-extending the thigh, the child lying prone. If the disease be in the upper dorsal and cervical region, this reflex spasm can be found in the muscles that go up to the head, passive movements being necessary to bring it out. Let the child then stand on the floor and raise itself on toes and balls of the feet, coming down quite heavily on the heels. This concussion is a very good test. Again, one can place the hand on the top of the child's head and press down, and concuss in this way. While the child is lying prone, the movements of the spinal column can be tested by placing the hand over the back, and with the feet and legs in the other hand, hyper-extending and moving them from side to side. Spinal tenderness to pressure over the processes is seldom present. It is the rule not to have any tenderness. This is true of children. In adults, however, tenderness in the rule.

Take, for instance, this child, who has been lying quietly under all this preliminary talk, and who gives no evidence of tenderness whatever as I run my finger along the spinal column, although she has a slight *bosse* or deformity. I find, on hyper-extending the thighs, a little reflex spasm; but, as I turn her over and crowd my fingers well down into the iliac fossæ, I encounter no marked tumefaction.

This other child, a girl about twelve years old, did present in the early stage of her trouble a deformity of the thigh. She walked with the right thigh flexed, and "hip disease" was diagnosticated. When she came under my observation, there was already a marked deformity, and she presented an abscess in the right iliac fossa, extending down under Poupart's ligament and showing itself again in Scarpa's space. A second abscess was found in the upper portion of the left thigh, front and rear, presenting a large tumor here. Under ether, the abscess on the right side was opened after the plan of Mr. Edmund Owen, of the great Ormond Street Hospital for Children, in London. His plan is to make a counter-opening in the ilio-costal space, and to cleanse the sac out as well as possible through and through. No reaction followed this procedure. The parts were

dressed with antiseptic care, and in a few weeks both wounds had closed. The abscess on the left thigh was opened anteriorly and posteriorly, a drainage-tube being carried through and through. The sac here was literally filled with bone detritus, and it required a long time to get the pieces of bone out from the meshes of the tissues. The result here was excellent; but after five or six months the sinus in the right ilio-costal space opened and discharged a little. Later on, the sinus on the posterior aspect of the left thigh opened again. The girl has had scarlet fever recently, and now, eighteen months after the opening of these abscesses, there is a slight discharge from each side. The case illustrates the unreliability of any method of curing these abscesses, and emphasizes the importance of maintaining excellent health and protecting the bone from trauma.

Treatment.—The treatment adopted, now, for this case, is to keep the parts clean about the opening, to apply simple dressings, to make for her a new plaster-of-Paris corset, to give her cod-liver oil and some assimilable preparation of iron. That which I prefer for children is the albuminate of iron. As the girl's health improves, I shall curette these sinuses, and inject them with the peroxide of hydrogen.

I prefer the plaster-of-Paris corset and the plaster-of-Paris solid jacket for the treatment of dispensary and hospital cases, because it is easy of application when the method is once learned, and because one can feel pretty sure that no one interferes with the treatment. It is well to bear in mind, however, that very few physicians know how to put on a plaster-of-Paris jacket. It seems so simple, that one does not care to waste the time in learning. This is evidently a mistake. If the gentlemen present can learn to apply plaster properly, I am very sure that good results can be obtained.

Take, now, this case about which we have just been talking. I have secured a seamless shirt. This is obtained of Lawson, 783 Broadway. It is made of Angora wool, is soft, fits well and is not very expensive. The plaster of Paris employed is obtained of the White Dental Manufacturing Company, is always reliable, comes in six and twelve-quart cans and does not require salt or alum in the water. It is very important to secure crinoline that is not sized with glue. That which is sized with starch makes an excellent bandage for the plaster, but if there be any glue in the sizing, the cloth should be washed before the plaster is rolled into its meshes. The bandages should be twelve yards long and from two and a half to three and a half inches wide, the plaster rolled well in; and when the bandage is finished you should wrap some tissue paper around it unless you expect to use it the same day. The padding over the salient points most serviceable is table felting. It is a double-faced Canton flannel material. The best position for a patient when a jacket is to be applied is partial self-suspension. The head portion of the swing is used, but the arm pieces are no longer employed. The arms are fully extended above the head, the hands grasping the wooden knobs on the rope, and by putting one above the other slowly, pulling down at the same time, taking care not to bend the elbows, just enough traction can be made to secure comfort. It is not necessary to get the heels from the floor. The next step is to have the patient pose. Get the column as straight as possible. With the seamless shirt pulled down and the felting over the salient points, such as the spinous processes, the anterior superior spines, and any projecting free ribs, the plaster bandages are applied, beginning at the bottom. A pail of warm water and one or two good assistants are necessary in order to make a neat jacket. As the bandage is rolled about the body and not pulled tightly, let each layer be rubbed well with the hand. This rubbing will enable one to determine where the weak points are, and these can be reinforced. Dinner pads are not employed. The jacket should be thin, not over one-eighth of an inch in thickness; even this is too heavy for children. The patient can remain suspended until the plaster sets, and this will require only a short time, especially if the precautions have been taken about good crinoline and good plaster. While the plaster is setting, the jacket can be trimmed out under the arms and in the groin. The thighs may be flexed in turn, so that barely enough of the jacket may be removed to enable the patient to sit down.

As this is a convalescing case, I propose to make a plaster corset of the jacket. So I cut down in front while the patient is still suspended, cut through with bandage scissors, loosen the straps at the top over the shoulders and then remove the jacket carefully, bringing it together immediately and holding it with a roller bandage. Any fur-

ther trimming of the edges can be done now. It is rolled up in some paper and placed over a kitchen range, on the space for warming plates. It is left here for twenty-four hours. After it is thus thoroughly dried, strips of leather, with shoe hooks attached, are sewed on in front, after the shirt has been turned up over the jacket and sewed at the top and after the edges in front have been covered with kid or chamois or adhesive plaster, as one likes.

Let it be distinctly understood that the corset must be used only in convalescing cases. In this next patient, an adult from California, who presents the lesion high in the upper dorsal region, I shall apply a solid jacket with a jury mast or head spring. I always employ a jury mast when the disease is above the seventh or eighth dorsal vertebra. I do not believe it necessary where the disease is lower than this region. The spring you see is made of heavy steel, and has chin and occipital straps; the frame work is fitted well to the back before the patient is suspended; and after the first two or three layers of plaster bandage, the frame thus fitted is applied, and the jacket is completed. As this patient has paraplegia from compression myelitis, and the compression myelitis is dependent on the Pott's disease itself, the recumbent posture will have to be assumed until he is able to move his limbs. The favorite treatment with me, in addition to the jacket, is to apply the Paquelin cautery, which I can apply above the *bosse*, and to administer large doses of potassium iodide. By large doses I mean from forty to sixty grains three times a day, continued for three months. Another important feature in this case is an immense abscess, which you see, extending from the *bosse* up to the occiput on the left side of the median line. This is to be opened freely, the contents evacuated, and the wound partially closed by suture.

As for abscesses, I do not interfere unless they are in the way of my dressings, or unless the patient is apparently suffering from their presence. As a rule, a cold abscess gives no constitutional disturbance. The cavity itself is a receptacle for the broken-down material of the bone and is harmless so long as it is not exposed to air.

The question as to how long a horizontal position must be maintained, or—what is of more importance to you gentlemen—how long before one can feel sure that convalescence is established, is difficult to answer, because the support to the column is so often defective, and for this reason the disease is perpetuated. If the patient could keep a good solid jacket applied for eight or twelve months without ever removing it, or if when it was necessary to remove the jacket a new one could be applied without disturbing the reparative process by any passive or active motion, then a year would be sufficiently long to continue this careful treatment. But the jackets break down sometimes very easily, the parts have not been well supported, and hence it takes from two to four years to bring about sufficient repair to enable a surgeon to give a good prognosis. The horizontal position is not maintained at all with this method of treatment. On the contrary, we let the patients lead an out-of-door life. If they are able to take the advantages of climate, we have them travel. In other words, we treat the case just as we would any tuberculous case.

The sign of convalescence are these: freedom from pain; no tenderness on concussion or jar; the improved condition of health and a general appearance of ankylosis. By "general appearance of ankylosis," I mean compensating curves above and below the bosse.

In conclusion.—1. The treatment of Pott's Disease of the Spine should be the application of a perfect fitting splint to the back so as to avoid all friction or irritation from the slightest movement. 2. The splint should be removed very infrequently, and, as a solid plaster-of-Paris jacket well applied must necessarily remain on a long while, this makes the best appliance for the average surgeon to employ. 3. The jury mast or head spring should be used where the disease is above the eighth dorsal. 4. Abscesses should be treated according to circumstances. No hard and fast rule can be laid down for their management. When they are opened, antiseptic precautions must be observed, not only at the time of opening, but on many subsequent dressings. 5. It requires from two to four years to effect a cure in this disease. 6. The appliances should be such that the patient can have the benefit of fresh air, an out-of-door life, and the best climate possible.

—Paronchynine is the name given by Dr. Schneegans to a new alkaloid extracted from herniaria glabra. The drug is official in Austria, and is employed as a diuretic.

TEALE AMPUTATION.—ABDOMINAL SECTION.—PRIMARY UNION AFTER AMPUTATION OF THE FORE-ARM.—SCHIRRUS OF THE BREAST.—PARTIAL ANCHYLOSIS OF THE KNEE-JOINT.

BY THOMAS G. MORTON, M. D.,

ONE OF THE ATTENDING SURGEONS TO THE PENNSYLVANIA HOSPITAL.

Result of a Teale Amputation.

Gentlemen: It has always been my habit to report to the class the progress of patients and results of operations presented here, so that you can complete your records of the cases. In conformity with this rule, I will state that the Teale amputation of the leg which you saw me do last week has progressed without a single unfavorable symptom. On the third day I dressed the stump and removed the rubber drainage-tube, which is of no use after the first few hours, and, as it is a foreign body, it should be dispensed with as promptly as possible. After this dressing, there will be no further occasion for disturbing the stump for several weeks, indeed, in all probability, not until complete consolidation has taken place.

Abdominal Section for Intestinal Fistula.

The man upon whom I performed abdominal section for fistula of the intestine has also done remarkably well. You recall his history. He had suffered with an acute attack of inflammation and abscess in the appendix region, or the right inguinal area; and this was believed to have been caused by perforative inflammation of the appendix vermiformis. The operation was undertaken last May; a lateral incision was made, and a large abscess-cavity was reached; but the appendix itself could not be found. The intestines were so involved in the inflammatory condition and so glued together by lymph, that further search for the appendix would have been attended with great risk of tearing the walls of the bowel. It was, therefore, thought best not to make a more extended search for it, after some fruitless attempts to discover it. However, the parts were thoroughly cleaned by removal of the sloughy tissue and exudate, the abdominal cavity was well drenched with hot water, and a glass drain was carried deep into the cavity of the pelvis. The patient subsequently made an excellent recovery, except that a small fistula remained, which gave evidence of being connected with the intestine.

The operation of one week ago consisted in re-opening the abdominal cavity; which was done in your presence. When I turned up the under surface of the cæcum, I found, as you remember, an opening directly into its cavity of sufficient size to admit the end of my little finger. This perforation occupied the site of the appendix, and unquestionably was caused by the sloughing off of the appendix at the time of the first attack, last spring. After first paring them, I brought the edges of this opening together with several Lembert sutures. After the belly-cavity was cleansed, and a glass drain had been inserted down to the lowest part of the pelvis, the wound of operation was approximated with interrupted silk sutures. The glass drain was syringed out every four hours for the first day, and then less frequently until the fourth day, when as there was no accumulation in the tube, it was removed and a rubber tube of smaller caliber was substituted. This in turn was cut away each day as the wound filled up, until at the end of the week, when it was dispensed with. Our patient bids fair to make a permanent recovery, as there is every reason to believe that the opening into the intestine has been completely closed by the sutures.

Primary Union after Amputation of the Fore-arm.

The patient whom I now present well illustrates the occurrence of primary union of the wound of operation after amputation of the fore-arm. He is 26 years of age, and was brought here two weeks ago, suffering with a crush of the hand and wrist, caused by a machinery accident. There has been only one dressing. It is now only fourteen days since the operation was performed, but the stump has entirely healed, and, as you see, it is quite firm. The man can now be discharged from the hospital.

These cases well illustrate the value of antiseptic surgery. In former times, suppuration always followed such operations; and secondary hemorrhage, blood-poisoning and pyemia were not uncommon. Now, if suppuration should occur, it simply indicates that the surgeon was not able to secure asepsis; generally because the rules governing this method have not been followed. I am

inclined to think, from my own observation, that the practice of using bichloride solutions which are too weak to disinfect the field of operation, by some surgeons, may account for their want of success in antiseptic work. I call attention to this, in order that I may tell you that, in my opinion, solutions of mercuric chloride made in proportion of 1 to 1,000 are not too strong when operating upon adults; of course a less strong solution should be used in the case of children, or when the skin is broken.

Carcinoma, or Schirrus, of the Mammary Gland.

The patient I now bring before you was admitted four days ago. She is 36 years of age, married, and has several children. She says that about eight months ago she accidentally received a blow upon her left breast, and that this was followed by pain, which continued. Then she noticed that the gland was becoming gradually hard, and the nipple altered in appearance. Her general health has also failed, and she sleeps poorly and has well-marked nervous symptoms.

The tumor, as you notice, is of considerable size and involves the entire gland. It is very dense and hard, but is freely movable upon the sub-mammary tissues, showing that it is free from connection with the parts below. The nipple is retracted and deformed; and upon pressure there exudes from it a watery fluid. The rapid growth of this tumor, its hardness, the attendant pain and the condition of the nipple, all indicate malignancy: that this is a carcinoma of the mammary gland. Unquestionably, in my judgment, this is a case of schirrus of the breast. Treatment may be palliative, or radical by removal of the diseased gland. Palliative treatment would consist in anodyne applications, the external use of the oleate of morphia and perhaps electricity, and the internal use of arsenic. I have little faith, however, in any such plan of treatment, but advocate early removal of the entire breast. A careful examination of the axillary region shows that at this time there is no involvement of the lymphatic glands in this situation; so that there will not be any necessity for opening up this region.

I will now proceed with the operation of extirpating the mammary gland. The breast is included between two elliptical incisions, the deformed nipple being nearly in the centre of the portion removed. After the skin is freely divided, as a rule, the gland can be torn out with the fingers aided by the handle of the knife as you observe. To the few bleeding vessels, I apply hemostatic forceps, and upon each a fine gut ligature, which is cut close and will be buried in the wound. The wound is necessarily large, and drainage is of great importance. I am now making at the bottom of the cavity an opening through the skin, towards the axilla, and through this incision I now pass the rubber drainage-tube. By this means more effective drainage is secured and immediate union of the wound is favored. The edges are brought together with interrupted gut sutures, and a piece of protective is placed over the line of the wound, and over this a thick layer of wet bichloride gauze, held in position by a gauze bandage, also wet with the same sublimate solution. Outside of this is a mass of dry bichloride cotton, which is also held in position by dry gauze bandages. Finally, a muslin roller bandage is applied over all, so as to confine the arm to the side, which completes the dressing.

Partial Anchylosis of the Knee-Joint.

This little patient, five years old, was admitted for treatment of partial anchylosis of the left knee. It is stated that about three years ago he received an injury which was followed by inflammation and abscess of this joint. Several fistulous openings resulted, which in time closed; but adhesions were formed between the condyles of the femur and the head of the tibia and the patella. These interfere seriously with the function of the joint, permitting very little motion. The angle of flexion is such as to prevent use of the limb in walking, constituting marked deformity.

The question arises, what can be done to give the child a more useful limb? If the leg cannot be extended by exerting a judicious amount of force, and without danger of causing a recurrence of inflammation, excision would be a better operation, because safer. With the exception of the elbow, the knee has been excised more frequently than any other joint, and with excellent results, now that we have absolute control over the dangers which formerly attended such operations by the adoption of antiseptic precautions in operating. The

propriety of excision, therefore, may now be properly considered in such a case as this.

The patient being fully under the influence of the anæsthetic, I will examine the joint more carefully. I grasp the thigh and also the leg, while I am making firm pressure upon the front of the joint. I find that, by exercising some force, I can bring the leg into very good position. I also ask you to notice that the hamstring tendons are not at all tense, so that their section will not be necessary. I place a well-padded straight splint underneath the joint, extending from the upper part of the thigh nearly to the ankle, and bind the limb firmly upon it.

In making an excision of the knee-joint, I always make a vertical incision, instead of a semi-lunar, or other section. I find that drainage can very readily be effected by piercing the skin on the side, for the passage of the rubber tube. In this way the wound of operation can be closed at once, and primary union can be obtained throughout its extent. If the patella is found in good condition, it can be divided vertically and retained. When this is done, its posterior aspect, or cartilaginous surface, should be removed; the patella will subsequently consolidate with the femur, and will materially strengthen the part. Of course, if the patella has been at all involved in the disease, it should be excised.

COMMUNICATIONS.

MEDICAL LEGISLATION.

BY J. M. TAYLOR M. D.,

CORINTH, MISS.

Public sentiment, both professional and lay, has always been divided on the subject of regulating the practice of medicine by legislative enactments. The opposition in the profession unfortunately includes some of its most distinguished members, although they are largely in the minority, yet when reinforced by the great horde of quacks and irregulars, claiming to belong to the profession, they have been able in some States to defeat or to cripple every effort which has been made to secure efficient legislation. Comprehensive and well-matured bills have been presented at various times in the several State legislatures, but through the positive opposition of some, and the indifference of other members of the profession in good standing, aided by those whose occupation was in jeopardy, they have been defeated, or so emasculated and mutilated as to fail to accomplish the intended objects of their authors. In every instance these laws have been mere compromises, and consequently have accomplished a very small part of what they should have done.

A very mistaken notion in regard to the intention of such legislation prevails, not only among the masses, but even among physicians otherwise well informed. It is believed by many that all such laws are designed to protect and benefit physicians as a class, and the constitutionality of these laws have been questioned in the courts as class legislation. But the question of constitutionality has been settled conclusively in the higher courts, and now it is only a question of æsthetics in the profession, and of personal interest among pretenders. The suppression of quackery by law would not only protect the people against the practices of the totally incompetent, but would elevate the profession and increase incalculably its efficiency in combatting disease, and in promoting health among the people. This no one can doubt. But the opponents of legislation say the profession is so noble, and its character so sacred, that it would degrade it to appeal to the law for protection. They say "let us not besmirch our garments with the filth of the law." But the law is not too filthy to protect us when maliciously prosecuted, or when we wish to enforce the collection of compensation for our services. Doubtless, however, our superlatively dignified brethren would scorn to resort to the law to collect their "bills." But if doctors' bills were ignored, and excepted from the operation of the law, these gentlemen would soon find it necessary to lower their dignity by resorting to some means to secure the filthy lucre required to supply their daily wants, thus degrading their exalted calling to the level of ordinary business pursuits. As long as necessity forces the doctor to place a money value on his services, and as long as he is compelled to rely on his practice for his bread and butter and the other necessaries of life, just so long must he submit to have his practice regulated by law on the same principles as every other business. The days of stilted dignity in the profession, which has always been more

a cloak for ignorance than real dignity, have passed away, and the tendency is now to consider all questions on their real merits.

Narrow-minded persons may suppose because the agitation of legislation to regulate the practice of medicine originated in the profession, that its advocates are actuated by selfish motives. But it requires only a little impartial consideration to see that it is the reverse. Any benefits that may redound to the profession will be wholly secondary and resultant upon the benefits conferred upon the population at large. Again, the objectors say "away with all legislation, let us have an open field for regulars, allopathics, hydropathics, homœopathics, botanics, eclectics, faith doctors, Indian doctors, and all the rest; then we shall have a survival of the fittest." This virtually admits the equal claim of all so-called systems to the confidence and patronage of the people—a very strange and inconsistent position for a regular physician to take! This kind of reasoning seems to result from a very illiberal and mistaken view of the objects of the proposed legislation. Protection for the profession or any faction of it, has been distinctly disavowed, and a careful examination of the various laws proposed will convince any unbiassed mind that the benefits are intended for the general public of all classes. The protection is for the people against incompetency, whether found in the regular profession or among homœopaths or hydropaths, or any other "paths."

The responsibility, then, for depriving the people of these benefits, and for continuing the gross impositions of quackery rests on those members of the profession who oppose legislation under the mistaken notion that it will lower the dignity of the profession. It is a fact which probably will not be denied by any one, that the non-professional public have always been willing and ready to accept and abide by any principles of conduct, or any line of policy that the members of the profession may agree upon. But if the profession stands back on its dignity, and perches itself on an utopian eminence above the ken of ordinary mortals, how are the people who are uneducated in such matters to appreciate the difference between the true and the false, between the physician and the pretender? If the self-inflated profession will continue to ignore the intelligence of the people, under the plea that its business is too exalted and recondite for ordinary minds to comprehend even the principles upon which it is based, what is to prevent the people from accepting as true the absurd, but plausible stuff with which the country is flooded by means of almanacs, circulars, and other means very well known. We may rest assured the enterprising promoters of quackery will leave nothing undone to delude and mislead the public mind.

No one understands the weak points in the policy pursued by the profession better than they, and they work them for all they are worth. Then let the people be instructed in everything necessary to enable them to distinguish the worthy from the unworthy. This instruction can only be imparted correctly by the profession, and it should be done by direct communication and systematic efforts, and not left to mere chance or accident. Until that millennium shall arrive, in the dim, distant future, when the people shall have been thus educated, let them have the benefit of protective laws. We have laws to protect virtue and morality, laws to punish murder, theft and crimes of every hue. Does anybody doubt the propriety of such legislation? Does the necessity for it indicate any doubt of the superiority of virtue over vice, or of the power of truth to overcome falsehood? We protect the people against the highwayman and the robber openly pursuing his occupation, and it is just as much the duty of government to protect the lives and health of the people from the incompetent and impostors as it is to protect their persons and property from the vicious and dishonest.

A CURIOUS CASE OF OPIUM ADDICTION.—MORPHIA BY NOSE.

BY J. B. MATTISON, M. D.,

MEMBER AMERICAN ASSOCIATION FOR THE CURE OF INEBRIETY, OF THE N. Y. NEUROLOGY SOCIETY; OF THE MEDICAL SOCIETY OF THE COUNTY OF KINGS; HOME FOR HABITUÉS, BROOKLYN.

Measured by the standard of a personal experience devoted to the study and treatment of this neurosis for nearly two decades, of all forms of continued opiate using among the better classes, in any walk of life, that from hypodermic taking is by far the most frequent. Morphia by the mouth ranks next. Then comes the use of the vari-

ous liquid preparations, and lastly, that of the crude drug. Among the lower orders, for obvious reasons, the reverse obtains. Probably few country shop-keepers do not include opium among their wares, to answer the demands of some habitués who rely on a daily supply quite as much as for their tea or tobacco. To this class the common term, "opium eaters," is quite correct; but for the former the misnomer is at once apparent. Only two opium eaters, strictly speaking, ever consulted me or came under my care. One was a most excellent and intelligent literary gentleman whom I had the pleasure of serving after he had been addicted for ten years to gum opium, reaching a maximum of thirty-six grains per diem, and using it after a somewhat peculiar fashion—a bolus of eighteen grains, twice a day, morning and noon; a six hours interval, and then nothing more for eighteen hours. This patient made a very gratifying recovery—dismissed on the twenty-sixth day of his treatment—and has since done himself credit by remaining well, and giving to the literature of the subject an interesting and instructive narrative of his case and cure.

Somewhat rare instances of habitual opium taking per suppository or injection are sometimes noted. I have noted only two.

The following case is quite unique, and so far as I know, medical annals have not a parallel. Dr. Von Klein's paper in the Medical and Surgical Reporter, November 1, 1890, makes it of special interest.

Mr. A., thirty-five years old, had been subject from boyhood to attacks of headache, sometimes occurring twice a week. After the age of fifteen these attacks decreased in frequency, seemingly because he led a more active out-door life; but during the next twenty years they never averaged less than one a fortnight. His general health was good and he was actively engaged in mercantile life.

In the autum of 1879, while suffering from a severe attack, a good (?) Samaritan, commiserating his discomfort, and learning the cause, suggested and proffered a certain medicine, which this party had found quite effective. This remedy was in liquid form, and to be used by *snuffing* five to ten drops, and if no relief resulted in twenty minutes, was to be repeated. Mr. A. gladly availed himself of this offer, and in a few minutes his headache was a thing of the past. Much elated at securing such rapid relief, and eager to possess himself of so great a boon, he asked the origin of it, and, in reply, was given the prescription number, with name and address of the druggist. Reaching town, he lost no time in providing himself with a supply of his newly-found panacea and for several months, quite unaware of its nature, had recourse to it with every recurring bout of pain.

In the spring of 1880 he began to have varied discomfort, apart from his headache, for which his migraine remedy also gave him relief. His suspicion, it seems, was now aroused, and he consulted the pharmacist as to its make-up, and was informed that it contained morphia, the prescription, in fact, consisting of ten grains of morphia to the ounce of water, of which the patient was directed to snuff from five to ten drops and to repeat in twenty minutes if required.

Even now not fully aware of his danger, he continued to use the remedy a time longer, when, for some supposed malarial trouble, he consulted a physician and apprised him of the situation, who, while uncertain as to whether the opiate thus taken would make itself a necessity, warned him of a possible peril, and advised its discontinuance.

The effort was now made to follow this advice, but with the usual result—failure. The attempt at self-cure, both by sudden disuse and by gradual decrease, was repeated many times, but never with success. So Mr. A. kept steadily to his morphia, increasing the amount from time to time, until he reached a maximum of one drachm in from four to eight ounces of water, per nares, each day. This was his regular stipend for eighteen months prior to coming under my care. Only once was any change made in the manner of taking. A short trial by the mouth caused so much gastric discomfort that the original method was soon resumed. The snuffing was repeated from three to eight times a day, beginning before the morning and ending with the evening meal. The invariable effect of any taken later was severe headache the next morning. All the opiate effect was obtained through the nasal membrane, as special care was taken to prevent swallowing it, and whatever amount returned or passed into the mouth was rejected.

During his addiction the man enjoyed marked immunity from his old-time headache, but this good fortune was not unalloyed, for the ill-effect of the morphia became decided, as shown by impaired eye-

sight, defective appetite, damaged memory, lessened avoirdupois, lost virile strength and desire, and an alvine torpor so marked that enormous cathartic doses were demanded—to say nothing of the minor discomforts with which every habitué is more or less familiar.

Such was Mr. A.'s condition on presenting himself for treatment. For various reasons it was deemed judicious to change the form of his opiate taking, so it was given by the mouth, and, after experiment, a morphia supply of from fifteen to twenty grains was found sufficient for his daily need.

Another leading indication related to his bowel inertia, and the initial attack in this direction was seven improved compound cathartic pills at bed-time, followed by a morning draught of two bottles of Hathorn water. This secured one moderate movement, and was repeated each evening, changing the laxative water to Hunyadi — of which a much smaller amount proved effective—and reducing the nightly pills, until, in ten or twelve days, they were dispensed with and the Janos water was relied on.

Special treatment was now begun; the quantity of morphia was gradually lessened; and in eight days the usual opiate was abandoned. The reflex results were not marked —mild restlessness, debility and insomnia being the most prominent. The former required no baths, the second was lessened by electricity—both currents—cold-shower baths and internal tonics; while full doses of fluid extract of Indian hemp sufficed to secure sleep. The stomach was undisturbed, except one slight vomiting, forty-five hours after quitting the opiate, and the maximum bowel movements were four during one day; usually there were only two or three actions daily. No astringent was called for. The patient did not lose a single entire night's sleep, and hypnotics were dispensed with in less than ten days. There was anorexia for several days, followed by an appetite so vigorous that indigestion resulted, and diet restraint was demanded. Signs of returning sexual strength were noted in less than a fortnight, and power in this regard was regained before the sixth week was ended.

The increase in weight was notable, averaging, for some weeks, nearly a pound a day. This, doubtless, was largely due—apart from the morphia eating—to his nutrient regimen, consisting of full feeding, emulsion of cod-liver oil with pepsine and quinine, in half-ounce doses thrice daily, to which was added five drops of Fowler's solution, and a constant current séance at bed-time.

This case teaches more than one lesson. It gives added proof of opium's ensnaring power, be the manner of its taking what it may. Doubtless this differs; and judging from the testimony of patients, the hypodermic method is most subtle and swift. But let no one, whatever the form, imagine himself safe, nor that he can control and abandon his practice at command.

NASAL CAUTERIES.[1]

BY EDWIN R. LEWIS, A. M., M. D.,
INDIANAPOLIS, IND.

In opening the discussion on the subject assigned me—Nasal Cauteries—I fear that my views may be considered one-sided; for, to my mind and with my experience, it seems that most of the so-called nasal cauteries have not much to be said in their favor and have much to be said against their recognition, except as relics similar to those exhibited in modern asylums for the insane. They have been advocated and used, but, now, we have a better way. London paste or Vienna paste or caustic paste in any form I never used in the treatment of nasal hypertrophies. I have patients under my care who wish that it had never been used on them. It is easy to see in their cases what harm has been done by its use. In the cases referred to it was used by specialists competent to make the best use of it. I once used nitric acid a great deal and have now a well-worn Smith's canula, attesting the faithful use made of it during one period. Many of my old patients still express gratitude for work which I did for them with strong nitric acid. Glacial acetic acid is kept in my office, but I never use it; and, although I once expected to do so in certain cases because of favorable notices made regarding it, I have never done so. Chromic acid in many cases has more to be said in its favor, certainly. In the treatment of posterior hypertrophies by means of a guarded porte-caustique, chromic acid can be easily and safely used, and the results are satisfactory in many cases. The general practi-

[1] Read before the American Rhinological Association, October 6, 1890, at Louisville, Ky.

tioner who is not provided with the apparatus of a specialist, and yet is called upon to treat nasal hypertrophies, will do well to use chromic acid in preference to any other caustic. Nitrate of silver needs to be mentioned only to be condemned in nasal treatment.

In my office and practice the galvano-cautery has taken the place of all other nasal cauteries. This is not a case of prejudice, I am sure, but a clear case of "survival of the fittest." The galvano-cautery does its work neatly, aseptically and, when properly used, painlessly and bloodlessly. It is under perfect control, and the cautery point or knife can be put exactly where it is wanted, and the action can be limited to the desired part. All this can be said of no other nasal cautery; at any rate, it cannot be said so emphatically and so truthfully.

There are many forms of battery used and recommended; and I have tried many. For all nasal operations except the removal of large growths by the loop, a small storage battery is the most useful and the most convenient. I have a small one in my office which is in daily use for all nasal operations requiring the cautery, with the exception mentioned above. In the office it is kept constantly charged from four cells placed in the cellar beneath. It may be easily detached in a moment, and taken out of the office and city, and used for days without being re-charged. For a loop, a larger or double battery is necessary; but even in that case the battery can easily be carried in the hand. A rheostat is attached to the battery for regulating the maximum heat of the electrode. This rheostat can be adjusted so that the electrode shall be heated to a dull red, a cherry red or even to a white heat. I have brought my small storage battery and a few fixtures for illustrating the method and explaining the minor but very important details. Properly used, the galvano-cautery gives most remarkably satisfactory results in many classes of cases.

To illustrate what is perhaps an old story, I select a few typical cases.

Case 1. Mr. K., 55 years old, was referred to me by Dr. D. A. Thompson, June 27, 1889. He had come from a distant part of the State to seek relief from a supposed ear trouble. He had suffered, as he said, for weeks from roaring and cracking sounds in both ears. He found it impossible to attend to any business satisfactorily and difficult to sleep. For many days he had felt pain in addition. Dr. Thompson found nasal hypertrophies; concluded that they were the principal, if not the sole cause of the trouble, and referred the case to me.

I treated the patient for a few days with a view to removing the irritation and reducing the congestion. There was a deviated septum, and very decided hypertrophy of both lower turbinate bodies. I cauterized on the fifth day, again on the eighth day, and again on the twelfth day, treating the patient daily in the intervals. He was then allowed to go home for a week, his relief from the roaring sounds being marked. He returned after ten days, and the cautery was used again. He left at the end of the week, thinking himself a well man. He has had no return of the ear symptoms to my knowledge.

Case 2. Mrs. C., 44 years old, was referred to me by Dr. J. C. Stillson. She was a victim of severe headache, the pains centering in the eyes and the pain in the right eye being intense. The tension was great, and there was some fear expressed of glaucoma. The engorgement of the turbinate bodies was great, and the nasal membrane was so exquisitely sensitive that it was with difficulty that cocaine could be applied on cotton. The relief after the action of the cocaine had been obtained was marked. In this case treatment was prolonged over several weeks before the cautery was used. The results were most satisfactory. The eye pains disappeared and the headaches became infrequent and slight. But with this relief the patient was content, and discontinued treatment, expressing hearty thanks. This summer she returned for further treatment, as the headache and eye pain were returning. She is now under treatment, having tried to get along without further use of the cautery, but she has decided to resort to it again. She says it does not pain her, but she dreads the idea of a cautery.

Case 3. Mrs. B., 35 years old, was referred to me by Dr. J. S. Thompson, May, 1889. She had used glasses for a few years, but lately had felt much pain in her eyes and was unable to read with any comfort. The chief trouble was in the right eye. Dr. Thompson found the glasses right, I believe, or possibly prescribed a slight change; but he suggested treatment for the nasal hypertrophy. She was unwilling to admit any nasal trouble, saying her nose was all right, but that her eye was the source of trouble. She fought it out, until friends and her hus-

band persuaded her to be treated by me. I found marked hypertrophy of the right lower turbinate body, treated it for a few days, and then cauterized it. The relief was great. The pain disappeared; reading became possible again; and in a few weeks this patient left me cured and grateful.

The above are typical of many cases where eye and ear troubles are relieved by the use of the nasal cautery. Simpler treatment directed to the nasal membrane relieves such troubles; but the cautery is called for where there is nasal hypertrophy, if the relief is to be permanent.

There is a class of throat cases best treated by the nasal cautery. Such cases come to us originally, or are referred to us by the family physician for treatment, because of some chronic trouble in the throat. I allude now to a class of patients who do not refer their trouble to their noses at all; they do not feel conscious of nasal disease; and when questioned they are apt to say, in many cases, "the nose is all right." Cross-examination brings out the fact that the nose is not all right, but the patient finds the chief trouble in the throat.

From 1884 to 1888 I was Professor of Chemistry in Wabash College, and during that period was called upon to treat the throats of a large number of students, especially at times of competition for prizes in declamation and oratory. It was noticeable that the worst cases were troubled with some form of nasal obstruction. When they were treated for the relief of such obstruction, it was found that the throat was benefited; in some cases where a nasal obstruction was removed by the cautery, the throat trouble entirely and permanently disappeared. To bring out the point I wish to illustrate, let us review briefly the treatment of simple, non-specific cases of chronic laryngitis, so-called, as given by those who write specially upon diseases of the throat. Mackenzie, Vol. I, page 211 (*Wood's Library*, 1880), says, "Local remedies of an astringent character are the most important agents in the treatment of chronic laryngitis." Seiler, in 1883, says the same. Sajous, in 1885, adds that all affections of the pharynx should be appropriately treated. Lennox Browne, in 1887, says: "The treatment of co-existent pharyngeal disease is of primary importance, many cases of laryngitis getting well if so treated higher up." Seiler, in his third edition, published in the latter part of 1888, recommends first of all the removal of the cause by the removal of nasal obstruction when it exists, getting still higher up for treatment. Rumbold, about the same time, says: "Chronic laryngitis is never idiopathic, it is always secondary;" and he puts it in large letters.

It is evident that there has been the evolution of a rational treatment of chronic laryngitis, in many cases, founded upon the recognition of causes not at all mentioned ten years ago, and until within two or three years barely referred to.

I will cite a typical case.

Case 4. The pastor of a prominent Presbyterian church came to me in 1887. He was a large, strong, healthy man, 42 years old. He had been finding it more and more difficult to preach, and for a year had been preaching with so much annoyance to himself that his work aggravated his complaint. He had studied elocution, and knew how to use his voice properly. He had consulted good specialists, and had been treated; but the treatment had been limited to the throat. The larynx was congested, the pharynx very much so, and its secretion was thick and sticky. The lower turbinate bodies were much hypertrophied; the left one so much so that the naris was almost completely occluded. Treatment was begun and confined to the nose, although his throat was troubling him so much that he did not care for the difficulty in breathing through the nose. The turbinate bodies were cauterized twice on the left side and once on the right side. It was not four weeks before he felt relief in his throat, although the treatment was conducted under difficulties, the patient coming to me from another city and continuing to conduct all his church services, including special services. He went off for a few weeks' rest, and returned, saying his voice was almost as clear and strong as ever. This patient comes to me occasionally for examination and one or two treatments. The larynx looks clear and healthy, although no treatment has ever been given it directly. The old symptoms, which threatened to compel him to give up his pulpit work, have disappeared.

A fourth class of cases comes to us, or are referred to us, because of nasal obstruction recognized as such, and manifesting itself as such.

We then have a large class of patients suffering from pain or disturbance of some kind in eye, ear, throat and nose, the cause of trouble in whom is referable to nasal ob-

struction. There are also many more or less obscure cases of various kinds, the trouble in whom is caused or aggravated by nasal obstruction. This fact is made apparent by the relief obtained from suitable treatment directed to the nasal membrane. Some patients are satisfied with such relief, and decline anything further, having a dread of all "operations." But the relief in many of these cases is temporary. Full and permanent relief can be obtained only by a radical reduction of the nasal hypertrophies. The snare may be used for removing large hypertrophies in the posterior part of the lower turbinate bodies. Chromic acid may be used for small hypertrophies in the same region; but in the large majority of cases the galvano-cautery is to be preferred. There is, then, in my opinion no one agent which gives relief in so many different cases, and gives that relief so immediately and permanently, as does the nasal cautery; and when I say nasal cautery, I am sure that I do not exaggerate when I say that I have more grateful patients whose gratitude has been won by the use of the galvano-cautery than I have of any other class. It remains, of course, to mention the cases in which the results have been of a nature to awaken criticism of the operation. These, in my experience, have been few, but they have been instructive.

Case 5. Mrs. G., 40 years old, was referred to me by her family physician. She was a victim of neuralgia, and had been unable to use her eyes for several weeks, when she came to me in May, 1889, because of the pain felt in them. Her physician, being the family physician of Mrs. C., referred to above as Case 2, it was thought by him that I might help her. Dr. Thompson had examined her eyes and found no error of refraction or ocular trouble to account for the pain. She was treated for eight days, and then the right lower turbinate body was cauterized, being hypertrophied. Relief was experienced, and in two weeks the lower turbinate on the other side was cauterized. The improvement continued, and in a few weeks the patient was in a much better condition than for a long time. Uvulotomy was performed in July, to relieve a slight cough that seemed reflex; and after that, there being a slight return of the pain in the eye, I cauterized again, and did so thoroughly. I found that I had gone too far. The reaction did not confine the patient to her bed, but the neuralgia returned, and for weeks she was as bad as ever; and although she thinks I helped her at first, she does not feel very enthusiastic now about the galvano-cautery. She is a patient of a decidedly neurotic temperament, has been an invalid for years, and I ought to have been satisfied with the early results and should not have cauterized so recklessly the last time. It undid all the former work.

Case 6. Miss H., 20 years old, was referred to me for pain in the eyes and headache. I found hypertrophied bodies and much engorgement of the same, and congestion of the entire nasal membrane and naso-pharynx. She wished to have the work done in as few days as possible, and as cheaply as possible; and so I gave but little preliminary treatment and cauterized very freely the left lower turbinated body. It is not often that the knife is sunk so deeply and freely as it was in this case. The next day her mother came to me, saying the daughter had a severe sore throat, fever, malaria, etc., etc., giving, in fact, an unfavorable report. I prescribed for her, and the mother went away. The following day a younger sister called, and reported that the family physician had been called who pronounced the case one of diphtheria. She was ill for two weeks or more, when she returned to me for further treatment, which I conducted more conservatively, and she was entirely relieved of the trouble which brought me to her originally. With all due regard for the physician's diagnosis, I have always felt a little suspicious of that case of diphtheria.

In a few other cases, and a few only, there has been severe "sore throat" and fever, which has necessitated calling in the family physician. These cases were all in persons to whom I had not given much preliminary treatment, or when I had attempted too much at one sitting, always urged to it by the patient. It has happened that some cases have had the cautery used immediately —that is, the first or second day of treatment—or have had large hypertrophies freely and sufficiently cauterized at one or two sittings with only a few treatments—the whole work begun and completed within a week or ten days—and with satisfactory results. Others want to have the same thing tried with them. The results may be satisfactory in the end to the patient who has not recognized the danger signals that have been flying, and who has not realized what

anxiety I have felt lest I had gone too far or too rapidly.

I would therefore recommend the galvano-cautery most highly and enthusiastically, but I would couple the recommendation with the following cautions.

1. Adopt preliminary treatment even if there is not much congestion or hyperemia. I request, and in some cases demand, to have the patient under my treatment two weeks at least before cauterizing; and in many cases I wish a longer time. The results are always more satisfactory after such preliminary treatment, and the work to be done by the cautery can be better gauged.

2. Cauterize in the anterior portion first and use the edge of the knife—not the flat surface—sinking it in as far as seems necessary and drawing it forward. It seems best to keep the knife moving; if stationary for a while it is apt to stick to the tissue. I usually apply the edge of the knife to the inside, pressing it outward and drawing it forward, then, if necessary, the edge to the lower part, pressing it upward and drawing it forward. One electrode may be used for both operations when one is skilled in it, or two electrodes may be used, one horizontal when introduced and the other perpendicular.

3. Spray the parts well, but gently, with soothing sprays, after cauterization. I use oil of vaseline with a little eucalyptol in it, then a warmed Seiler's solution, and finally oil of vaseline again, medicated as before. The medicated oil is varied in different cases. Sometimes I use oil medicated with iodol.

4. Never cauterize on both sides at one sitting. I make no exception to this rule in my own practice.

5. Introduce the electrode while cold, apply it to the posterior part of the hypertrophy to be cauterized; then press the knob to heat the electrode, and begin to draw it forward. The maximum heat has been determined before by the regulation of the rheostat. I prefer a bright red turning to white, and obtain the best results from such heat. In this respect I confess that I do not agree with or understand Lennox Browne (3d Edition 1890, page 141) unless he refers to the heat required in the ear and throat and elsewhere. A black heat I never use; a dull red heat is apt to make the knife stick; a bright red heat, even if inclining to white, is to me the best. It must be remembered that the electrode is cooled considerably by the secretions, and by the body when made to enter it. The thumb should be withdrawn from the knob before withdrawing the electrode, so that it may be withdrawn cold.

6. The parts should be treated gently and soothingly for several days after cauterization; the secretions being removed and the naris cleansed with as little irritation as possible. If the other side is to be cauterized, a week should be allowed to intervene, if possible, before doing it. I recommend that the anterior part of the hypertrophy be cauterized first. If the hypertrophy is so large that it requires it, the next operation may be begun further back, and so on until all is removed at several sittings. Sometimes after a satisfactory cauterization of the anterior part, the posterior part can be easily removed with the snare, when it would have been very difficult to use the snare on the entire hypertrophy.

I apply the cocaine by means of cotton on a probe, using a fresh 10 per cent. solution. The cotton is gently applied to the anterior part, held in position a few seconds, then gently and slowly pushed back. Care is taken to have the sides and lower part of the hypertrophy well moistened with the solution, although the cotton must not be so saturated that the solution will run into the throat or drop on the floor of the naris. In a few minutes the parts are ready for the cautery. There is absolutely no pain; rarely is there a drop of blood; and the after pain in the great majority of cases is *nil.*

In a few cases there is slight nausea felt at the close of the application of the cocaine, or during or after the use of the cautery, *i. e.*, in perhaps one per cent. of my cases. In such cases a little wine or brandy is given, and the disagreeable feeling passes off. Never have I seen anything more alarming than that; if that can be called alarming.

—The Ambulance Surgeon has a rather unfortunate time of it. If he is behindhand he is abused; if he is in too much of a hurry he is blamed; if he thinks the patient will die on the way, and refuses to take him, he is censured; and if he takes the patient, and does get him to the hospital alive, the victim is announced to have been hustled to death. This is not a perfect world; but, take it all in all, our city ambulance system is probably better than that anywhere else. —*Medical Record.*

Foreign Correspondence.

LETTER FROM INDIA.

Bombay Hospitals and Dispensaries.

Bombay does not lack in hospitals and dispensaries. The influence of affluence in raising such charity organizations by the native grandees is as praiseworthy as well directed. The greatest of the hospitals in India—nay throughout the British empire with but a single exception of Guy's Hospital—is the "Jamshedjee Hospital," justly so called from the name of its benevolent founder, a Parsee grandee. Its extensive compound, with a number of small subdivisions of the hospital, forms quite a little town in itself. The hospital can well accommodate one thousand patients freely and easily. A vigilant watch has ever been kept over it, to keep it most scrupulously clean and hygienic in every respect. It is in this hospital that medical students are trained for the profession. It is the most accessible one of all, from all quarters of the city. The next hospital is the European General Hospital, but it is not one-sixth so large as the "J. J. Hospital." Another is the G. T. Hospital"—the initials being those of the founder's and his father's names. It is located on the border of the most thickly inhabited part of the town. It is maintained by the Bombay Municipality. In its close proximity is the "Cama Women Hospital," built by another Parsee grandee. At first the hospital was under charge of Dr. Pichy Phipson, an American lady physician. Recently it is placed in charge of Miss Annie Walk, a medical licentiate, with Dr. Pichy Phipson as the visiting physician. Very objectionably close to it, and to all intents and purposes looking like its mere extension, is the "All Bliss Obstetric Hospital," and its name implies the purpose which it has been exclusively built for. This is yet another charity offshoot of Parsee munificence. The "C. J. Ophthalmic Hospital" is in the extensive compound of the "J. J. Hospital." This hospital too is raised by another Parsee millionaire. Being unnecessarily high, it looks more showy than useful, because one very commodious flat for indoor patients can be easily formed out of it. At one end of the city is the "Lunatic Asylum," established by the government; and its position is the most suitable one for the purpose it is meant to answer.

Now leaving hospitals aside, and coming to dispensaries, we observe that the "J. J. Hospital Dispensaries" (male and female) have the largest average daily attendance of about 150 in each section. All classes and conditions of meagre and miserable patients gather themselves there, for whom benches and chairs to sit on are altogether out of consideration. Next to it is the "G. T. Hospital Dispensary." Then there is a separate dispensary for women and children in charge of Dr. Pichy Phipson. Besides these charity dispensaries conducted by the government, there are others, *e. g.*, the "A. H. Wadia Dispensary," the "C. J. Ready Money Dispensary," the "M. N. Petit's Dispensary," all established and maintained by opulent Parsees, deriving their names from those of their founders, and attended by graduates of Bombay University.

Periscope.

Treatment of Lupus Vulgaris.

In concluding his letter from Paris to the *British Journal of Dermatology*, November, 1890, Dr. Louis Wickham gives the following as Dr. Brocq's opinion on the course to follow in the treatment of a case of lupus vulgaris.

Dr. Brocq says: "Having reached the end of this long study of the means actually employed in arriving at a definite cure of lupus, I hear the majority of my readers exclaim: But how shall we make our choice in the midst of all these methods? which process must we choose? None, I reply, to the exclusion of all others. This is eminently an occasion for eclecticism; long experience with the patient ought to tell the medical man what he ought to do, and, in my opinion, he will, in following his cases, have to have recourse to various means. This is, I can assure you, no mere invention on my part; indeed, I am only repeating what for many years certain English and American dermatologists have asserted.

"On uncovered places everywhere where it is indispensable to have a united, smooth, supple and regular cicatrix, in the face particularly, preference should be given to scarification. On the body, on the extremities, wherever the beauty of the scar is not an absolute necessity, recourse should be had to the galvano-cautery, to the thermo-cautery,

or even to scraping. In lupus of the mucous membranes these latter methods should also be chosen. These are the indications drawn from the site of the disease.

"Cases of lupus other than those of typical vulgaris should be treated by the actual cantery or by local caustics, and by antiseptics, such as sublimate, pyrogallic acid, salicylic acid, pure or associated with pyrogallic acid, lactic acid, mercurial plaster, red mercurial plaster, camphorated naphthol, iodoform, aristol, iodized glycerine, etc.

"The verrucose tubercles and the condition which was formely designated by the name of lupus sclerosus papillomatosus ('anatomist's wart' ought to be placed under this heading) may be treated very successfully by scraping, but since the time of the bacillary theory, they have been preferably destroyed by the hot iron.

"Lupus vorax will be stopped in its extending course by crossed linear scarifications carried out according to the rules previously laid down, the wounds being subsequently dressed with sublimate mercurial plasters or dry powdering with aristol and iodoform.

"But what must be done for typical lupus vulgaris? I do not hesitate to declare that here again no one procedure must be employed to the exclusion of all others. I believe especially that cauterizations and scarifications may be combined with the greatest possible advantage in the same subject; that is what I call the Mixed Method; I have used it for many years, and it has given me most successful results. This is my view of it.

"When we have to deal with a lupus at its commencment, when it is still superficial and in a vigorous subject, if it be situated on a visible part, it must be scarified, washed with sublimate, dressed with mercurial plaster, or with sublimate compresses. In this way a complete cure is rapidly obtained, without the slightest apparent cicatrix. If, however, some of the lupus nodules persist with some tenacity, it is of great advantage to touch them several times with a fine galvano-cautery point, finishing up by a few repeated scarifications to improve the scar.

"When we have to attack an ordinary lupus of somewhat old standing the opportunity of scarification and actual cauterization depends much on accessory conditions. If the subject is not in good general health, if he excites doubts as to the highly infectious nature of the affection, it is first of all to cauterization that we must turn; it must be used as long as is possible, and the scarifications only employed towards the end of the treatment to improve the cicatrix.

"If the subject, although healthy, presents an exuberant lupus, turgid, very extended, it is still useful to commence with cauterization, either with fine points or especially with the galvano-caustic grating, in order to reduce it, to weaken it, and in some measure to diminish its mass. But the cautery must not be continued too long; above all things it must not be used too deeply, and the aspect of the scars must be studied with the greatest care, for there are many patients who have a most deplorable tendency to form keloids as a consequence of too vigorous cauterizations. I think, therefore, that when the mass has been sufficiently reduced the patch ought to be subjected to several scarifications in order to improve the scar and render it more supple. The cauterizations may be repeated briefly for a short interval, if their utility be proved; if, for example, there are still a few persistent tubercles lying in the midst of healthy tissues; then the case is finished by scarification at several sittings.

"It must not be supposed that these sittings make the duration of the treatment much longer. After what I have seen, I am persuaded of the contrary. I have already written, in 1886, that when lupus is treated by scarifications, recourse must be had to cauterizations as soon as the useful effect of the scarifications passes off, and *vice versa*. I am now more than ever convinced of the truth of this precept, that by changing the method several times during the course of treatment of a lupus a much quicker cure is attained then when only one single procedure is adhered to. By the preceding combination scars are obtained incomparably nicer than those produced by the cautery alone, and in a much shorter time than if scarification alone is employed.

"In cases of lupus with isolated tubercles the galvano-cautery must be used at first, and scarification at the finish. But where the disease is situated on spots in which it is important to avoid the slightest cicatricial contraction the latter process alone must be employed.

"Lupus of the nasal fossæ must be attacked by electro-cauterization when it is possible, or better by scraping, combined with cauterizations with perchloride of iron, nitrate of silver, lactic acid, dressing of cam-

phorated naphthol, with cod-liver oil, boracic ointment, iodoform, iodol, or aristol.

"Lupus of the conjunctiva and that of the cornea will be treated by scraping and scarification. Those of the buccal and pharyngeal cavities by the electric cautery and by cauterizations with iodine, nitrate of silver, lactic acid, balsam of Peru, camphorated naphthol.

"When it is desirable to work very quickly, even at the expense of some marked scars, we strongly advise the employment of the radical surgical treatment, which is held in such great honor in certain foreign climes. The patient is chloroformed; everything is scraped out which is possible without producing too great a destruction, and in the surfaces thus prepared the deeper tubercles are sought out, and either enucleated by means of small curettes or cauterized one by one with the nitrate of silver point or the galvano-cautery. To render cicatrization more rapid powders of iodoform and aristol may be used, and it will be then seen if it is necessary to undertake another complete operation, or to confine one's self to a few cauterizations or scarifications.

"Thus we reject no method. At times we have thought well to lacerate the isolated nodules and then to cauterize them with nitrate of silver. We have already spoken of the rôle which we give to sublimate, mercurial plaster, iodoform, iodol, aristol, and subcarbonate of iron in the final dressings. We employ in like manner ointments, sublimated collodion, salicylic acid and pyrogallic acid plasters when the patients are compelled to suspend the surgical treatment, and we alternate these various preparations with red and gray mercurial plasters.

"When we have once begun to treat a lupus it must never be left alone for a single instant until a complete cure is effected.

"All this long exposition can be summed up in one word. There is no one uniform, invariable treatment of lupus which suits all patients alike. The dermatologist must have sufficient experience and medical tact to act according to circumstances, and to know how to pick out that therapeutic method which is most suitable to the particular case, and to the period of its treatment."

The Bladder in Infants.

In an interesting paper on the pelvic viscera in the infant, in the *Edinburgh Medical Journal*, October, 1890, Dr. J. W. Ballantyne says:

The bladder of the infant is even when fully distended almost entirely an abdominal organ. In the six months' fetus, a male, he found the bladder, which was distended with clear, pale-yellow urine, lay almost entirely above the pelvic brim, only a small part of the lower and posterior segment lying below that plane. In the case of a full-time male infant in which the bladder was very greatly distended with urine, a still smaller part of the lower end of the viscus lay below the pelvic brim, in the plane of which lay the vesical openings of the ureters. In the case of another full-time male infant in which the bladder was only partially filled with urine, the same relation of that viscus to the plane of the brim was found to exist. In the cases of three full-time female infants, in all of which the bladder was empty, an almost inappreciable part of the vesical cavity lay below the plane of the brim. Symington states that fully half the bladder in the infant lies within the cavity of the true pelvis and below the plane of the brim. The specimens above mentioned do not show this disposition of the bladder, but in three of the cases (two male and one female) there existed a circumstance which may serve to explain the difference in position of the bladder. This circumstance consisted in the presence of a loop of the lower end of the descending colon or of the upper end of the sigmoid flexure within the pelvic cavity, lying in the female infant in the right part of the utero-rectal pouch, and in the male infants in the recto-vesical pouch. In the other female infants the bladder was empty, and was not therefore distended at its lower end; and it must not be forgotten that in them there lay part of the *uterus* within the pelvic brim. In the case which Symington figures in his *Atlas*, in which half the bladder lay in the pelvis, the infant was a male, therefore there was no uterus to fill up the brim, the bladder also was distended, and bulged backwards towards the sacrum; and further, there was no loop of sigmoid flexure in the pelvis, the posterior vesical wall lying in contact with the rectum, and the recto-vesical pouch being empty. If the pelvis contain in addition to the rectum a twist of sigmoid flexure, and more especially if the subject be a female, it is difficult to see where room can be found within the pelvis for fully half the bladder. The ar-

rangement of sigmoid flexure to which Dr. Ballantyne alluded is, he believes, a very common one in the infant, and he finds that Jacobi in the *Archives of Pediatrics*, 1888, p. 204, makes the statement that "the sigmoid flexure is bent upon itself several times in the narrow pelvis of the infant." In the case of male infants in whom no loop of sigmoid flexure exists in the pelvis, and in which the bladder is distended, that organ may be found lying to some extent below the plane of the brim; but in the female infant, where the uterus partly fills up the brim, and in male infants, where the sigmoid twist occupies the pelvic inlet, the above-described position of the bladder must be the usual one. The bladder is, therefore, practically entirely an abdominal organ at birth.

In Dr. Ballantyne's specimens the vesical orifice of the urethra lay very nearly at the level of the upper border of the symphysis pubis, and in all only a very small part of the vesical cavity lay behind a line dropped vertically through the orifice of the urethra. The position of the upper end of the bladder varies with the state of distension of the viscus. Of three cases in which the bladder was empty, in two its upper end lay 2.3 ctms. above the symphysis pubis, and in the other case (in which the infant was frozen in the genu-pectoral position) it lay 3 ctms. above the level of the symphysis. In one case in which the bladder contained a little urine, its upper end was 2.5 ctms. above the symphysis; and in another case in which the bladder was enormously distended, its upper margin was found 2 mms. above the umbilicus (4.5 ctms. above the symphysis). It is probable that the empty bladder in the infant reaches nearly half way to the umbilicus.

In the infant the anterior vesical wall is in close contact with the anterior abdominal wall, and there is no intervening pouch of peritoneum. The reflection of the peritoneum from the anterior abdominal wall on to the posterior bladder wall usually takes place a little below the level of the umbilicus, and from 2 to 3 ctms. above the upper border of the symphysis pubis. In one case in which the bladder was over-distended, Dr. Ballantyne found that the peritoneum passed to the posterior surface of the bladder about the level of the umbilicus. The anterior surface of the bladder, triangular in shape, is, therefore, entirely uncovered by peritoneum, a fact of great importance to the surgeon who may be contemplating operative interference for stone. Posteriorly the peritoneum passes over the bladder wall, reaching in the male infant to a point immediately below the vesical orifice, and here coming into relation with the small prostate gland, another fact which is of great importance surgically. In the female infant the peritoneum does not descend so low posteriorly, for its point of reflection on to the anterior uterine wall lies above the level of the internal urethral orifice. In the infant the posterior relations of the bladder are less constant than are its anterior relations. In one male infant the bladder was related posteriorly to a loop of sigmoid flexure, and to the commencement of the rectum; in another the anterior surface of the cæcum was in relation with the posterior vesical wall, but in this case the cæcum lay mesially, and was therefore abnormal in position; in a male fetus of six months the bladder was related posteriorly to the rectum and to some coils of small intestine; and in yet another premature infant with dropsy, the posterior bladder was in contact with ascitic fluid which lay in the recto-vesical pouch of peritoneum. In the female infants the bladder lay in close relationship with the uterus posteriorly, but in one case there intervened a loop or two of small intestine, which lay in the utero-vesical pouch of peritoneum, and in this case also the right Fallopian tube lay behind and a little to the right side of the bladder, being also in the utero-vesical pouch. The hypogastric arteries run laterally to the bladder, converging towards the umbilicus.

The badder is relatively small in infants, and this fact is at least one of the causes of the frequency of micturition in infants and young children. When empty the cavity of the organ measures from 2 to 2.5 ctms. in length; but that the bladder can in exceptional circumstances be greatly distended with urine is proved by one of my cases in which its upper wall reached to a point 1 or 2 millimeters above the umbilicus. It is rare for the bladder to contain more than 1 drachm or 1½ drachms of urine at a time at birth.

Menstruation and Pregnancy after Removal of Both Ovaries.

Mr. J. Anderson Robertson, of Glasgow, reports a curious case in the *British Medical Journal*, September 27, 1890. He says that on May 4, 1888, a woman 23 years old was

brought to him. She had begun to menstruate at 13½, and was regular until three years and a half ago, when she began to be irregular. From this time the quantity became less and less, and the length of time between the periods became greater until September 14, 1887, since which date she had not menstruated. The pain during these three years and a half had continuously increased in strength and duration until now, when, she said, "I am never free from it." It extended from both ovarian regions round to the top of the sacrum, and was always worst in the left ovarian region. For some time past the patient has been "spitting blood every day;" at times merely a trace, but occasionally as much as "three tablespoonfuls" of bright red blood. She had constant leucorrhœa; bowels loose; micturition normal. The patient was a warehouse girl, and had to support a younger brother and sister; but latterly had not been able to work regularly. She was pale and ill-looking and very thin.

On examination Mr. Robertson found both ovaries enlarged and very tender, and recommended immediate removal of both ovaries, as the woman had already undergone a long course of treatment, in spite of which she had been rapidly getting worse. As some of patient's friends objected to surgical interference, medicinal treatment was again tried, and other advice sought and acted upon.

In January, 1889, patient came back, saying that she was quite unfit for work, and that she would rather die than live in such constant pain and misery. Her friends were now willing to have anything necessary done, and agreed as to the utter futility of further treatment by medicines.

On January 26 Mr. Robertson removed both ovaries. The left ovary was much enlarged, and was cystic. The right ovary was also considerably enlarged, with the capsule much thickened, affording evidence of long-continued ovaritis.

The patient made an uninterrupted recovery. Her temperature never rose above normal, and her pulse was only once above 80, namely, on the evening of the day after operation, when it reached 90. She rapidly improved in health and appearance; the pain entirely ceased, as did also the "spitting up" of blood; and she soon got plump and well looking.

On April 25 she began to menstruate (four days, quantity moderate, no pain). Normal and painless menstruation for a like period again took place in May, and continued regularly until October. In June the woman married, and in September she was looking strong and well, and feeling, as she said, "better than I have been for years; indeed, I am quite well and happy." She ceased menstruating on October 25; and on August 13, 1890, was confined. Dr. Kennedy, who attended her, said that the child (a male) was twenty-four inches long and weighed nearly 10 pounds. The labor—a difficult and protracted one—had to be terminated by the aid of forceps, and the child, unfortunately, was still-born. The mother did well.

Mr. Robertson says that from this very interesting case we may learn several lessons. Amongst these are:

1. The truth of Mr. Lawson Tait's teaching regarding the starting point of menstruation, namely, that the ovaries are not causative of it. In fact, in this case the presence of the diseased ovaries prevented it, and when they were removed normal menstruation followed.

2. The possibility of vicarious menstruation. The woman had brought up blood daily for months, but this ceased after removal of the ovaries, that is, when normal menstruation became possible, and it has not recurred.

3. The proof that removal of both ovaries does not necessarily render a woman sterile. Mr. Robertson adds that he was not aware of leaving any ovarian tissue. His aim was to extirpate the ovaries thoroughly and he thought he had done so. He suspects, however, that a small portion of healthy ovarian tissue had reached up to or beyond the hilus of the right ovary, and that this may have taken on regular ovarian functions. This, of course, is merely conjecture.

4. That in performing double oöphorectomy, excepting in cases of uterine fibroid, any apparently healthy portion may perhaps be left.

Surgery or Electricity in Gynecology.

Dr. Anna M. Fullerton, in concluding a paper published in the *Annals of Gynecology*, November, 1890, says that the conclusions suggested to her mind, after several years' work in the Woman's Hospital of Philadelphia, where a very large gynecological prac-

tice affords especial facilities for the study and treatment of the class of cases referred to in this article, are as follows:

First. Temporary conditions of acute pelvic inflammation, due to non septic causes, are quick, as a rule, to respond to the ordinary palliative measures for allaying inflammation, such as the use of salines, rest in bed, etc. If properly treated, they are likely to get well without leaving any permanent lesion behind them.

Second. For the treatment of pelvic disease, the use of electricity, even in skilled hands, has proved uncertain in its results, and is fraught with possibilities so dangerous as to preclude its use as a therapeutic agent in the manner at present advocated.

Third. When the history of a case, and careful and intelligent examination prove a pelvic malady to be of long standing, and a source of persistent ill health, it is poor practice to waste time in prolonged palliative treatment when an exploratory incision can clear up the obscurity and prepare the way, at least, for intelligent management.

Fourth. In acute cases, where masses are found in the pelvis, and the accompanying history and symptoms point to the probability of the existence of conditions which delay may render dangerous, there should be early and prompt resort to operation.

Fifth. For the attainment of satisfactory results from such operations the skilled workman is required; therefore their performance should be delegated to the few whom natural gifts, training and surroundings enable to attain a high degree of excellence in abdominal and pelvic surgery.

Sixth. All gynecologists should not consider it their duty to attempt this work, which constitutes a distinct and comprehensive branch of surgical science.

Seventh. All physicians should be more thoroughly trained to appreciate the existence of conditions demanding the care of a specialist, and should be more disinterested in referring such early to the proper sources for help.

As regards methods, asepsis, Dr. Fullerton believes, is to be preferred to antisepsis in abdominal surgery. The little details, which vary with each operator, owe their comparative value to the efficiency with which they enable this principle of asepsis to be observed, and with which they expedite the thorough and rapid execution of an operation.

Strictly Milk Diet in Scurvy.

M. M. Tchelzoff, in the *Bolnitchnaya Gazeta Botkina*, February 21, 1890, recommends an absolute milk diet in scurvy. This year during the epidemic of scurvy in Russia, 148 patients were admitted to the hospitals, of which 30 were subjected to absolute milk diet. The 30 cases treated by the author were extremely severe ones, presenting œdema of the legs and especially of those limbs that were more subjected to exercise.

For the sake of experiment, some of the selected cases were put in the beginning on a mixed anti-scorbutic and milk diet, from four to five glassfuls of milk being given daily. The improvement in these cases was very slow. An absolute milk diet was then substituted, beginning with from four to five glassfuls of milk and increasing the quantity of milk from one-half to one glassful a day, no medicine being administered. The author's conclusions are:

1. An absolute milk diet aborts the scorbutic process in any period of its course.

2. With the above method of treatment there is no recurrence.

3. With the above method, convalescence is established much quicker than with the ordinary anti-scorbutic treatment. Thus, out of twenty-eight cases, nineteen recovered in eight days. On an average, five cases recovered in two weeks, and four cases recovered in three weeks.

4. The addition to the milk of the smallest amount of any other article of diet protracts the recovery.

A Fasting Heroine who Succumbed.

The *Weekly Medical Review*, quoting the *Hospital Gazette*, asserts that Zelie Bourrion, the fasting girl of Bourdeilles, in the department of the Dordogne, who endeavored to emulate the feats of Tanner, Succi and Jacques, has recently died at her home. Her constitution was completely shattered after her fast of thirty-three days. When she returned to her cottage she tried to eat a little, but her stomach was unable to bear the food, and she succumbed in a few days. Her fate will serve as a warning to any persons of her sex and class who may have been tempted by the notoriety which she obtained by her fast to follow in her footsteps.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE MODERN VIEW OF DISEASES OF THE UTERUS.

Modern pathology of the diseases of women, as built upon abdominal surgery and upon post-mortem work, has wrought a revolution in our conception of what have been called diseases of the uterus. This is especially true of diseases of the uterus when complicated by pelvic inflammation. When such pelvic inflammation was considered to be cellulitis, caused by and kept up by disease of the uterus, and only to be cured by removing the supposed causative disease, uterine disease occupied a pre-eminent place in the field of pelvic disease. But now it is known that cellulitis is a rare condition, and that what was formerly regarded as cellulitis by the clinician, is really inflammatory disease of the uterine appendages. It is undoubtedly true that endometritis precedes salpingitis; but it is not true that the endometritis or other uterine disease keeps up the salpingitis. On the contrary, the salpingitis keeps up the endometritis, either by causing pelvic congestion or through the escape of catarrhal products from the tubes into the uterus. This fact was recognized even by some of the older authorities; but it is only through the light of modern pathology that it has become perfectly plain.

The influence which these facts have upon our conception of pelvic disease, and upon their treatment, becomes apparent immediately. Under the old theory, in these cases of mixed pelvic disease, the practitioner directed his treatment to the uterus, in order to cure the uterine disease and thus remove the cause of the complicating cellulitis. This was perfectly logical; but experience has shown that the method is futile and even dangerous; and recent discoveries have brushed away the apparently logical grounds upon which the system of treatment rested.

The disappointments and the disasters resulting from the old methods of practice are now clearly explained. That the practitioner failed to cure pyo-salpinx, hemato-salpinx, hydro-salpinx, or abscess of the ovary by making applications to or doing operations upon the uterus, was the natural consequence of misdirected efforts. And attacks of peritonitis not infrequently resulted from the treatment because manipulation of the uterus loosened adhesions about the tubes and permitted the escape of septic material into the peritoneal cavity.

This great advance in knowledge must be of signal advantage in the treatment of the diseases of the uterus. The elimination of this mixed class of diseases from consideration, at once renders the indications for specific lines of treatment the more certain, and the results to be obtained the more positive.

The dangers heretofore encountered have certainly been due to operation upon mixed cases, or to inefficient antisepsis, and with proper discrimination in the diagnosis and

selection of cases for operation they can be avoided in the future.

LEPROSY IN NEW SOUTH WALES.

The *Australasian Medical Gazette*, October 15, 1890, contains some interesting Editorial comments on a proposed "Leprosy Bill" for New South Wales. After stating the proposition of the law on September 18, the *Gazette* says: "Though we are of opinion, notwithstanding the four known cases in this colony in which the disease has attacked persons of pure European descent, that there is no reason for alarm, yet we think it well that the health authorities should have legal power to isolate cases of leprosy if, in the general interest, it is found desirable. Where the surroundings and mode of life of the household in which the case is found are good, we do not think there is really urgent reason for the removal of the infected person, for all experience goes to show that under such circumstances the disease is not easily communicated. But if it should make its appearance in a household in which diet, cleanliness and the other sanitary necessities are habitually neglected, the removal of the first victim will be advisable, as probably preventing the infection of the others. Though the Board of Health has isolated at the Coast Hospital each case as discovered, it has done so without legal authority, which it will not possess until this bill becomes law. It is not advisable that any public body should, even in the public interest, be obliged to act arbitrarily and illegally as a consequence of the neglect of the Government of the day to its often repeated representations and remonstrances."

The bill of which our contemporary gives an epitome provides that persons becoming aware of the presence of leprosy in any person shall notify the authorities, and that the Governor may by proclamation direct that any suitable place be set apart as a lazaretto for the reception and medical treatment of lepers, and may make regulations for the safe custody of lepers. Upon receiving a report of a case of leprosy, the Board of Health is to cause investigation by two or more legally qualified medical practitioners, and upon being satisfied that such person is suffering from the disease may order the removal of such person to the lazaretto and detention there until released by order of the Board of Health, or isolation in such place or manner as the Board may direct. The order is to be in writing and signed by the president or secretary or any two members of the board, and may be addressed to a member of the police force or other person as the Board may consider expedient. Any person wilfully disobeying or obstructing the execution of any order of this nature, trespassing on the lazaretto or other place, or communicating or improperly interfering with any person detained therein, is to be liable to a fine.

While we fully agree with the *Australasian Medical Gazette* as to the small need for such alarm as the discovery of lepers in English-speaking countries has recently excited, we also agree with it in granting so much to popular prejudice and to a timidity on the part of the profession which may have more grounds of justification than we can see, as to approve of the Government's setting aside a place for lepers and authorizing their isolation there.

PIRACY BY MEDICAL PUBLISHERS.

In this number of the REPORTER, under the head of Notes and Comments, we publish a letter written by Dr. Wm. Murrell to the *British Medical Jonrnal*, which expresses the indignation of a number of British medical authors at the way in which their books have been, to use their expression, "pirated" by an enterprising publishing house in New York. We do this in the interest of international justice and courtesy, and in order that, as far as the REPORTER reaches, the medical public in this country may be informed of a procedure which is

likely to be regarded as a discredit to it by our brethren who read the *British Medical Journal.*

Some of the books alluded to in the list given by Dr. Murrell were long ago sent to the REPORTER for review, but no notice was taken of them, for the reason that we had good ground for suspecting that they belonged to a class of publications which is severely condemned on both sides of the Atlantic Ocean. It looks now as if there were some chance that the United States House of Representatives would before long pass the International Copyright Law which has already been passed by the Senate. This is a law for which the REPORTER has more than once expressed sympathy and approval, and when it is upon the statute books, such occurrences as are criticised in Dr. Murell's letter will be illegal in this country, as they are now, in our opinion, immoral.

We are perfectly aware that the sin of piracy is not confined to the United States, and that English publishing houses have committed quite as heinous offenses against what authors believe to be their moral rights. But the fault of our neighbors is no excuse for our faults; and it is proper for those who have an interest in morality, to endeavor to correct what is wrong in their own country, and to trust that any efforts they may make to correct wrong-doing in others will have more force if they are able to show that they themselves are not sinners in precisely the same way.

AMERICAN ACADEMY OF MEDICINE.

The American Academy of Medicine held its fourteenth annual meeting in the Hall of the College of Physicians of Philadelphia, December 3 and 4, 1890. The object of this Society is to bring into closer relations with each other medical men who are alumni of classical, scientific and medical schools, and generally to encourage efforts to secure and maintain a high standard of education among physicians in the United States.

At its last meeting discussions took place in regard to the best way of attaining the objects in view, and a few papers of purely medical or hygienic interest were read.

The REPORTER is in hearty sympathy with the purposes of the American Academy of Medicine, and for that reason rejoices that it meets periodically and stirs up the profession, very much in the manner suggested in a paper read by Dr. Gihon for Dr. Gerrish, with the title: "Tithing Men."

From our Editorial post of observation we see very well how many different agencies must labor to bring about the standard of education to which we believe the medical profession in our country ought to attain; and we wish success to every one of them—including that one which has just held its meeting in this city.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

SAUNDERS QUESTION COMPENDS No. 14. Part I. Essentials of Refraction and Diseases of the Eye. By EDWARD JACKSON, A. M., M. D., Professor of Diseases of the Eye in the Philadelphia Polyclinic and College for Graduates in Medicine, etc.

Part II. Essentials of Diseases of the Nose and Throat. By E. BALDWIN GLEASON, S. B., M. D., Surgeon in Charge of the Nose, Throat and Ear Department of the Northern Dispensary of Philadelphia, etc. With 118 illustrations. Small 8vo, pp. viii, 268. Philadelphia: W. B. Saunders, 1890. Price, $1.00.

This is a very good number of the series of Question Compends issued by W. B. Saunders. The first part, by Dr. Jackson, goes over the subject of refraction and diseases of the eye with characteristic carefulness and thoroughness. It is, indeed, an admirable summary of our present knowledge of this subject. Dr. Gleason's part of the book is also well done. There are one or two points in regard to it, however, capable of improvement. One that we note, is the recommendation of the use of the compressed antiseptic tablets now manufactured from Dr. Seiler's formula, without any special directions in regard to dissolving them. Experience shows that they are by no means so easy to dissolve as one might be led to expect, and if Dr. Gleason knows some way in which they can be quickly dissolved, it might be well to bring it to the attention of those less familiar with the matter. There are also some evidences of lack of care in the writing or proof-reading of certain prescriptions, which we trust will be corrected in any succeeding edition. On the whole the book is one which we can recommend as both convenient and useful.

Notes and Comments.

Piratical American Publishers.

Dr. William Murrell writes to the *British Medical Journal*, October 11, as follows:

"May I beg your assistance in exposing a glaring case of publisher's piracy of which I have the misfortune to be one of the victims? In November last I published a small book on the treatment of chronic bronchitis. Soon after its appearance, I entered into an arrangement with Messrs. P. Blakiston, Son & Co., of Philadelphia, for the production of an American edition, which was issued in due course. I have just received information from them that Messrs. Wm. Wood & Co., of New York, have reprinted it, not only without my permission, but without communicating with either my English or American publishers. It would appear that there are firms in New York who appropriate the property of their trade colleagues with as little compunction as they do that of British authors.

"On looking down Messrs. Wm. Wood & Co.'s list of publications, I found the names of many of our best known medical writers, and I was curious to learn whether they had been treated with the same want of courtesy which I had experienced. I accordingly communicated with several of them, and the result has been a string of indignant letters, the writers one and all protesting strongly against the unauthorized reproduction of their works.

"Dr. Dickinson says: 'The information in your letter that Messrs. Wood have reprinted my lectures on the Tongue is new to me. They did the same for my book on *Urinary Diseases*. I have, of course, given no permission.'

"Sir Henry Thompson says: 'I had not heard of the republication of any work of mine by Messrs. Wood & Co., of New York, until you named it.'

"Mr. Bryant says: 'I had no idea my book had been republished in America. It has certainly been done without my permission.'

"Mr. Jonathan Hutchinson says: 'I certainly never gave any permission to Messrs. Wood to reprint my *Pedigree*. In a recent *Atlas of Skin Diseases* a large portion of the plates are mine, without, so far as I can find, a single word of recognition.'

"Dr. Richardson says: 'Wood & Co., of New York, not only pirated my essay entire, but did so in face of my protest.'

"I have received similar communications from Dr. George Harley, Dr. Thin, Mr. Keetley, Mr. Mansell Moullin, Dr. Simon, of Birmingham, Dr. Sinclair, of Manchester, Mr. Mark Hovell, Dr. Lloyd Tuckey, Dr. Whittle, of Brighton, and many others. The only exception is in the case of Dr. Currie, who states that he was offered 'an insignificant percentage'—which, he adds significantly, 'has not up to the present time been received.'

"I believe that there is a popular impression that Messrs. William Wood & Co. pay the authors whose works they appropriate, but I cannot find that there is any foundation for this belief. I have talked the matter over with a good many of my American friends, and they are naturally indignant at the manner in which we have been treated. There is, unfortunately, no international copyright law, and we presumably have no legal redress. A constant exposure of such instances of piracy may, it is hoped, eventually ensure adherence to the first principles of commercial morality."

Congenital Ranula.

Mr. D. Edgar Flinn, F. R. C. S. I., surgeon to St. Michael's Hospital, Kingstown, Ireland, says, in the *Dublin Journal of Medical Science*, October, 1890, that in a paper read before the Moscow Medical Society, Müller states that in the Foundling Hospital at Moscow four or five cases of congenital ranula had been observed during a period of seven years in about 80,000 children; and the *London Medical Record* of December, 1877, makes mention of the fact that, up to that period, there were only two known instances of this affection on record—one published by Dubois in 1833, and a second, of more recent date, by M. Lombard. Mr. Bryant records two cases; both were, probably, he states, congenital, and came under his notice when the patients were about twenty years old. Sir W. Fergusson records one case. Ranula was formerly thought to be due to an obstruction of the salivary ducts; but recent authorities seem to favor the theory that it is caused by obstruction of one of the mucous glands that are situated beneath the tongue. But, as Fairlie Clarke says, although the term ranula is applied to large tumors sometimes

found below the tongue, they are analogous to the sebaceous tumors which are met with on the skin, and, like them, contain a thick, gritty, putty-like substance, somewhat offensive in odor. The mucous membrane beneath the tongue is, furthermore, often the seat of cystic formations, which take their origin sometimes in the ducts of the sublingual and submaxillary glands, sometimes in the areolar spaces, and, possibly, also sometimes in the bursa, between the genio-hyo-glossi muscles. To all these cystic growths, whatever may be their exact pathology, the term ranula is applied.

Mr. Flinn then described a case of ranula analogous to the sebaceous tumors found on other portions of the body. The growth was noticed on the second day after birth, and the subject was—when Mr. Flinn saw him—very nearly twenty-nine years old. On examination, at first sight, he gave the impression that he was suffering from acute glossitis. It was with great difficulty he could articulate, and it was impossible to understand what he said. The tumor very nearly filled the cavity of the mouth, and the tongue was pushed upwards and backwards, and could hardly be felt with the tip of the finger. The tumor also projected beneath the jaw into the mylo-hyoid space, and assumed an elongated shape in this situation, being about five to six inches in length. It was hidden from view by the patient's beard, and was as large as a good-sized orange. The projection into the cavity of the mouth commenced to cause inconvenience about some eight months prior to the date of his admission to the hospital, and for over a month the man had experienced difficulty in swallowing, and subsisted principally on liquid nourishment. He daily essayed to get some particles of solid food down, but it was quite an ordeal to do so, as it required a good deal of manipulation to get the food to the back of the mouth. There was a continual dribbling of saliva, and for a week previous to my seeing him he was unable to sleep or lie down in a recumbent position for fear of suffocation. On examining the tumor, fluctuation was quite evident in the mass in the mouth, but in the neck it partook more of a solid nature.

The treatment was to aspirate that portion of the mass within the mouth, when about fifteen ounces of a creamy fluid was drawn off. This gave great relief. The man could now speak more distinctly, but found it difficult to move his tongue forward. The tumor rapidly filled again in the mouth, and was aspirated a second and a third time, large quantities of a similar fluid as before being drawn off at each aspiration. The mass in the neck now became softer, and deep-seated fluctuation could be detected. It was then decided to lay open the tumor from the neck, and a deep incision gave vent to four ounces and a half of thick, brown pultaceous matter, rather offensive in odor. Mr. Flinn then scooped out the remainder of the cavity, and took away a good deal of cheesy and grit-like substance. After this the cavity suppurated, and there was a free discharge of pus for a week or so. A short time subsequently the patient left the hospital freed from the unsightly mass that had disfigured him for so many years.

In the case under notice, the patient stated that so long as he can remember he had had a swelling about the size of a small Spanish nut lying beneath the tongue, which caused him little or no inconvenience, excepting that, at some times more so than others, he had a slight difficulty in articulating plainly. The parents both said they noticed this swelling when their son was but a day or two old. It gave them very little concern, as it appeared so small and did not seem to interfere with the movements of the tongue, the child being able to suck freely and protrude the tongue. At this time it was about the size of a small pea, and remained that size for some years, then got a little larger, increasing to the size of a small nut. It remained then stationary until some fifteen months ago, when it commenced to increase rapidly in size, and interfered with the movements of the tongue. No assistance or treatment was ever sought for, as the sufferer had a dread of surgical interference; and if it were not for the fact that he went within measurable distance of both starvation and suffocation he would, probably, not have given his consent to any ameliorative measure being adopted.

Some Objections to Cocaine in Genito-Urinary Surgery.

Dr. Joseph B. Bissell, M. D., attending surgeon to the Dispensary of Bellevue Hospital, says, in a paper in the *Medical Record*, November 1, 1890, cocaine is of almost universal application in such operations as circumcisions, internal urethrotomies, meatotomies, etc., and is usually attended with

complete success as an anæsthetic. There are, however, some disadvantages following the use of the drug, and I wish to briefly relate a few of them. Since cocaine has been in use it is not uncommon to find, after an internal urethrotomy, one or two pieces of mucous membrane clinging to the urethrotome. They are usually found in the angle between the dilating-bars and the short cross-bars. In these operations the Otis urethrotome, an instrument which is very nearly perfect, is always used, and used with the utmost care. After the cutting, the bars are only closed sufficiently to admit of its withdrawal. In about one-quarter of all the cases there was found caught in the instrument one or more pieces of membrane. In some cases the portion torn out was of considerable size. In a recent operation it was over half an inch long and nearly a quarter of an inch at its widest point.

Where ether is used in the internal operation with perineal section this accident is not noticed. In order to be still more certain that the cocaine caused the trouble, I made applications of cocaine to normal urethræ, and into urethræ with large caliber strictures, as if about to perform internal urethrotomy, waited the usual time for it to absorb, and then, through the endoscope, observed the condition of the urethral wall. There was a little more difficulty than was natural in entering the proper sized tube. The mucous membrane was blue and congested, and pointed into the opening of the tube. In the pathological urethræ these appearances were most marked. This narrowing of the canal and fulness of the mucous membrane would account for the frequency with which the latter is caught and torn away by the smallest closing of the bars of the instrument. Further stricture or permanent contraction of the penis will be a very natural result of this laceration. Hemorrhage after the operation is another disadvantage of cocaine. Bleeding during the first night is more likely to occur after cocaine anæsthesia than after ether or chloroform, as can be observed in cases of external section. This hemorrhage is not of much importance in hospitals, or where a competent nurse is in charge; but when the care of the patient is left, as it often has to be, to a lay friend, it may be a very serious matter.

In circumcision cocaine rarely gives trouble during the operation. If the solution is injected too close to the line of the cut, the swelling it causes may obscure the edges and leave a ragged and irregular line of union. The extravasation of blood, which is almost unavoidable where the cocaine is injected into the subcutaneous tissue is objectionable. In some cases superficial sloughing of localized points may result from this extravasation and make the healing slow and troublesome. A very serious objection to cocaine in circumcisions is in children or in very nervous patients. The sight of the instruments, the dressings, the pain of the hypodermic punctures, and feeling and hearing the cutting and sewing up of the wound will cause severe shock in a delicate and sensitive child, and may frighten him into hysterics or even convulsions.

Chloroform is so easily given and so harmless in children under ten years, that it or ether ought to be used in preference. Idiosyncrasy may account for certain cases in which the drug, however skilfully applied, does not completely anæsthetize. Other cases occur in which the tissues, owing to pathological changes, do not absorb the solution rapidly enough, or sufficiently, in the quantity it is safe to use, to cause complete freedom from pain.

Cocaine poisoning is always possible, even with moderate quantities of the drug. Some people are much more liable to cocaine intoxication than others. One of my patients whom I circumcised for an old inflammatory induration of the foreskin, developed serious constitutional symptoms; but after waiting over half an hour I operated without any local anæsthesia whatever. The patient was a man twenty-eight years of age, and of good habits. I injected forty minims of a six-per-cent. solution. During the operation, which lasted about three-quarters of an hour, he complained of dizziness, inability to see and nausea. His pulse was 100 to 120, full and bounding. After the operation he went soundly to sleep, and, though easily awakened, he was unable to walk for several hours. He recovered completely in about six hours after the operation.

Examination for Tubercle Bacilli.

The *Druggists' Circular*, December, 1890, says that Dr. H. Kühne (*Centralblatt für Bakt. und Parasitenkunde*), after referring to the fallacies and difficulties with which the search for tubercle bacilli in sputum from phthisical patients is surrounded, describes a new method of staining the bacilli.

When it is difficult to spread out the sputum on a cover glass he uses a concentrated solution of borax, to which at least an equal quantity of sputum is added. The mixture is shaken up in a suitable vial or is worked up in a mortar, after which it is easily spread in a thin layer over the cover glass. Nummular sputa from cavities may be broken down with a watery solution of carbonate of ammonium; this has the advantage that it is partially volatilized as soon as the cover glass is heated, and what remains is broken up by the action of the acid. An equable layer on the cover glass being obtained, the albumin is coagulated by careful heating over a flame, after which the specimen is stained in Ziehl's fuchsin solution for five minutes, the color is completely removed with a 30 per cent. solution of nitric or sulphuric acid, and the specimens are washed in water and dried. In order to obtain a contrast stain, two or three drops of a concentrated solution of picric acid in anilin oil may be added to a watch glass containing pure anilin oil; a drop of this, placed on the slide before the cover glass is lowered into position, gives a sufficiently yellow contrast stain to cause the red tubercle bacilli to stand out very prominently. They may be examined with a magnifying power of from 60 to 100, and where they are in great number, as is the rule in "cavernous" sputa, they appear under still weaker magnifying power as particles of red dust on a yellow ground. To make a permanent preparation, Kühne recommends that the anilin oil be driven off by means of his hand blower and that the specimen be mounted in Canada balsam. By this method the tubercle bacilli only are stained.

Enlargement of Liver in a Child.

Eliza W. Dunbar, of Zurich, in the *Bristol Medico-Chirurgical Journal*, September, 1890, describes the case of a little girl three years old who showed such an increasing enlargement of the abdomen as to lead to medical advice being sought. The enlargement on examination she found to be entirely due to increase of size of the liver, which reached in its lowest boundary to a line drawn across the navel. Traces of rickets were present, but in a slight degree, and there was no deformity of the thorax such as would be followed by displacement of the liver. The little girl had during the short period of her existence shown always an extraordinarily large appetite, to appease which she had frequently been found eating paper in large quantities—newspaper and also card-board. According to the mother's statement, the child ate habitually largely, was unrestricted as to quantity at meal-times, and required as much as her brother who was 14 years old. Often the child procured food between meals. Latterly many dainties refused by an invalid in the house had been eaten up by the child. She was well, except for a little diarrhœa, which soon ceased when appropriate remedies were used. Also she had been seen to pant a little after running upstairs, a symptom which soon disappeared after treatment had begun.

Every organ was sound with the exception of the liver. Though it was enlarged, it was quite painless however pressed. Temperature was normal and urine contained no albumin.

Considering the history of the case, the enormous appetite and recent means of extra indulgence, the painlessness, and the healthy state of heart, lungs and kidneys, Dr. Dunbar diagnosticated accumulation of fat in the liver. The treatment consisted chiefly in restricting the diet, and after six months' time the liver was found to be of normal proportions.

Mattison Prize.

With the object of advancing scientific study and settling a now mooted question, Dr. J. B. Mattison, of Brooklyn, offers a prize of $400 for the best paper on "Opium Addiction as Related to Renal Disease," based upon these queries:

Will the habitual use of opium, in any form, produce organic renal disease?

If so, what lesion is most likely?

What is the rationale?

The contest is to be open for two years from Dec. 1, 1890, to either sex, and any school or language. The prize paper is to belong to the American Association for the Cure of Inebriety, and be published in a New York medical journal, *Brooklyn Medical Journal* and *Journal of Inebriety*. Other papers presented are to be published in some leading medical journal, as their authors may select. All papers are to be in possession of the Chairman of Award Committee, on, or before January 1, 1893.

The Committee of Award will consist of Dr. Alfred L. Loomis, Pres. N. Y. Academy of Medicine, Chairman; Drs. H. F. Formad,

Philadelphia; Ezra H. Wilson, Brooklyn; Geo. F. Shrady and Jos. H. Raymond.

Electric Light as an Analgesic.

The *Boston Medical and Surgical Journal* cites Von Stein, of Moscow, in *La France Médicale*, as reporting several cases of different painful affections which have been relieved as if by magic by the electric light. The apparatus which he uses consists of a small incandescent lamp about two inches long, with a reflector in the shape of a funnel, which is applied directly to the skin over the seat of pain. For the head and neck it is left in position for ten or fifteen seconds, but for other parts of the body it remains from one to five minutes, or until the patient complains of the heat. The author has obtained remarkable results in cases of intercostal neuralgia, rheumatic pains of the shoulder, lumbago and severe pain in other parts of the body. The number of applications for permanent relief differs much, sometimes one being all that is necessary.

NEWS.

—Dr. C. L. Miller has removed to the N. E. corner of Seventeenth and Christian streets, Philadelphia.

—Dr. Charles A. Miller, Superintendent of the Longview Asylum for the Insane, near Cincinnati, died November 21, 1890.

—Dr. J. L. Stewart, a well-known surgeon, died in Erie, Pa., on Saturday, December 6, aged 86 years. He had just returned from the Medical Congress in Berlin.

—Members of the medical staff attached to the Philadelphia Hospital and District Physicians for 1891 were chosen December 8 by the Board of Charities and Correction.

—A woman, living near East Dubuque, Illinois, is said to have given birth to a child without eyes and with no place in the head for them. The forehead extends down to the nose perfectly smooth.

—Dr. L. Webster Fox, who recently resigned the position of Ophthalmic Surgeon to the Germantown Hospital, was elected Emeritus Ophthalmic Surgeon by the Board of Managers at their December meeting.

—The election of a Professor of Materia Medica, General Therapeutics and Hygiene, lately filled by Dr. Roberts Bartholow, was, on December 8, indefinitely postponed by the Trustees of the Jefferson Medical College.

—Dr. Edward M. Hartwell, associate in Physical Training and Director of the Gymnasium at Johns Hopkins University, has resigned to accept the position of Director of Physical Training in the public schools of Boston.

—The Camden, N. J., Homœopathic Hospital, which has been open for five years, has closed its doors and its property is for sale. The reason assigned by the Managers is the difficulty of securing medical attendance at the hospital without compensation of the medical men.

—Surgeon General Baxter, who was stricken with paralysis December 1, died in Washington December 4, without having regained consciousness. The funeral took place December 6, from All Saints' Unitarian Church, and the interment took place at Arlington Cemetery. Five foot battalions, a platoon of light artillery and two troops of cavalry acted as an escort. The War Department was closed at noon on the day of the funeral.

—The American Academy of Medicine held its fourteenth annual meeting in Philadelphia, December 3 and 4, Dr. Samuel J. Jones, of Chicago, presiding. The following were elected officers of the Academy for the ensuing year: President, Dr. Theophilus Parvin, of Philadelphia; Vice-Presidents, Dr. Henry M. Hurd, of Baltimore; Dr. Alonzo Garcelon, of Maine; Dr. Robert L. Libbett, of Carlisle, Pa.; and Dr. Richard J. Dunglison, of Philadelphia; Secretary, Dr. Charles McIntire, Jr., of Easton, Pa.; Assistant Secretary, Dr. Edgar M. Green, of Easton, Pa.; Treasurer, Dr. J. Cheston Morris, of Philadelphia.

—Acting Secretary Nettleton has informed Customs officers at New York, Boston, Philadelphia, Baltimore, Norfolk, Portsmouth and Newport News of the appointment of Veterinary Inspectors at those ports by the Secretary of Agriculture, and has instructed them to hereafter refuse clearance to vessels carrying cattle or sheep until they shall have received notice from the said Veterinary Inspectors to the effect that the cattle and sheep in question have been duly inspected in accordance with the regulations of the Agricultural Department. The following is a partial list of the Veterinary Inspectors: At Boston, Dr. A. B. Rose; at New York, Dr. C. B. Michener; at Norfolk, Baltimore and at Newport News, Dr. G. C. Faville.

FAIRCHILD'S

PANCREATIC TABLETS.

Afford a convenient, effective, and elegant means of administering the ferments of the pancreas.

These tablets can be given at any interval prior or subsequent to the ingestion of food, at the discretion of the physician, without entailing inconvenience to the patient.

In cases of intestinal indigestion, what can be a more rational practice than the introduction of the pancreatic ferments at the time when the gastric digestion is spent, and no obstacle is offered to their passage into the intestinal tract?

Pancreatic ferments bear no dependence upon an alkaline reaction. They are exceedingly active in neutral solutions and are not rendered inert by a merely acid reaction. It is, therefore, only at the height of *normal* gastric acidity that the pancreatic ferments may be theoretically held to be inoperative in the stomach. The ferments of the pancreas—known to digest rapidly every form of food, starches, fats, beef, milk, fibrin, etc., have proven useful as remedies, *per se*, notwithstanding the prejudice of theoretical views and conclusions based upon experiments under conditions purely artificial and differing in important respects from those in which their employment is indicated.

BURN BRAE
A PRIVATE HOSPITAL
--FOR--
MENTAL and NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

EXTENSIVE AND BEAUTIFUL GROUNDS, affording perfect privacy and pleasing variety. House and surroundings unusually attractive and cheerful. Heat, light and ventilation perfect.

A PLEASANT, SAFE AND HEALTHFUL HOME,
With constant professional supervision. Music, games, open-air amusements, boating, etc., are provided for patients.

THE OLDEST INSTITUTION OF THE KIND IN THE UNITED STATES.
Both sexes received. A limited number of opium habitues admitted. Pleasant companions for female patients.

LOCATED A FEW MILES WEST OF PHILADELPHIA,
At Primos Station, on the Philadelphia and Media Railroad, from Broad Street Station, Philadelphia, Pa.

Clinical Lectures.

CHOREA OF ADULTS.—VIOLENT LEAD POISONING—PNEUMONIA OF DRUNKARDS.[1]

BY J. M. DA COSTA, M. D.,

VISITING PHYSICIAN TO THE HOSPITAL, ETC., ETC.

Gentlemen: The first case which I show you to-day is one which is both etiologically and therapeutically of very considerable interest. It is a case the history of which is as follows. The patient is a colored man, thirty-nine years old, a barber by occupation. His father died of heart disease; his mother and sister were affected with chorea, developed after they had reached adult age. His mother's chorea lasted for twenty years, and she eventually died from the effects of the disease, as did also his sister. The patient's attack came on after his thirtieth year. His case belongs, therefore, to the group of adult choreas. As far as we can ascertain there is no history of rheumatism in his family, nor has he ever had rheumatism. The patient has always been healthy until seven years ago, when he began to have choreic attacks without any appreciable cause. Without any history of injury, fright or rheumatism, he gradually became affected with these violent choreic movements, which have been increasing in intensity, and on his admission to the hospital were so violent that he was confined to his bed, where he remained until the first of this month. These movements ceased at night, and sleep was undisturbed. In this respect his case resembles that of his mother and of his sister.

Now, let us examine the patient's heart to see if his disease is in any way connected with a cardiac lesion. The movements are so violent, the chest even constantly moving, that it is very difficult to analyze the cardiac sounds with accuracy; but by taking time, I am able to tell positively that there is no cardiac disease here. The first sound is a little heavier than normal, and the second is distinct, but there is no murmur present. The urine is normal. The temperature has been rather sub-normal, never exceeding 98°, and at one time falling to 97°. He has no headache; and no cerebral symptoms beyond an occasional slight giddiness. His tongue is clean, and there are no digestive symptoms. The pupils are of moderate size and react to light.

This patient is a striking illustration of that comparatively rare disease, hereditary chorea of adults, an affection which is a very much more severe disease than is the chorea of children. The fact that it usually does not occur until adult age, and that it appears without any cause and as the result of an hereditary influence, gives rise to an unfavorable prognosis, one far less favorable than in the ordinary chorea of childhood and adolescence. Also we do not see in these cases the relapses or ameliorations which occur in ordinary chorea. Here the disease is continuous. The patient is never free from the disease. There are, it is true, exacerbations in this man's condition, occurring about once a month without apparent cause. We may look upon this disorder as one of those strange neurotic affections which may be likened to other hereditary nervous diseases, such as hereditary epilepsy, hereditary ataxia or Friedreich's disease, which also occur in family groups. Most likely the hereditary weakness lies in some of the nervous motor centres in the brain, but this is not positively known.

Now, as regards treatment. This man has improved under the use of Fowler's solution, nine drops daily. But when I came on duty, I placed him on what has done him yet more good, namely, the one two-hundreth of a grain of the hydrobromate of hyoscin, three times a day. This is a de-

[1] Delivered at the Pennsylvania Hospital.

cided dose. Hyoscin is a very active agent, and I have seen toxic effects arising from the one two-hundreth of a grain. It benefited the patient much, and it is therefore incumbent upon us to continue the treatment. We will give him larger doses now, the one one-hundred-and-fiftieth of a grain three times a day. If this should not succeed, I shall try hyoscyamin, from which also I have seen excellent results. It is a kindred remedy to hyoscin, and both produce excellent results in instances of long-standing chorea. Should this fail, remembering a very violent case of long-standing chorea in a young adult in the ward, I should place the patient on belladonna, pushed until its toxic effects are produced, or chloral, keeping the patient under its influence, even half drowsy, all of the time. Considering the obstinate character of these hereditary choreas, I fear we shall have an extended opportunity to test these drugs. Along with them, we shall give a nourishing diet, and insist on his having an out-door life.

Lead Poisoning.

Here is a case of violent lead poisoning, in a man twenty-nine years old. He has been working in lead works during the last four months to within four days of his admission, on the third of this month. About a month ago he noticed a sweetish taste in his mouth, and about two weeks ago a blue line on his gums. At times he has had pain in his back, legs, arms and abdomen, and for the last ten days he has had wrist-drop. It is truly a classical case of lead poisoning. During the last seven days the pain in his abdomen has become very intense. It is referred to the umbilicus, and is twisting in character. His bowels are very constipated, his abdomen is scaphoid and sensitive to the touch. The urine is non-albuminous. His tongue is heavily furred, and salivation is profuse. He was placed on ten grains of iodide of potassium three times a day, and sulphate of magnesia to keep his bowels open. On the fifth of November he began to vomit, and his bowels on that day were copiously moved. On the eighth, he suffered intense pain and was given an hypodermic of morphine and atropine to control it, and, for his sick stomach and colic, tincture of cannabis indica, ten drops three times a day. A quarter-drop dose of croton oil was given four times daily, to move his bowels; but these not acting, we resorted to magnesia sulphate, one drachm in solution with two drops of dilute sulphuric acid and ginger. This proved more effective. Since then he has continued to improve. His bowels are in a much better condition, and during the last few days he has been placed upon the sulphate of strychnine, the one-fiftieth of a grain three times a day. His temperature has been slightly elevated, but not materially so. To-day he still presents evidences of lead cachexia in a marked manner, and there is still some wrist-drop. He is not able to move his extensors. There is also slight wasting of the muscles of the thumb, along with double wrist-drop of a moderate degree. There is a very marked blue line around the teeth of both the upper and lower jaws, but more so upon the lower. The tongue is now clean. There is still some sensitiveness of the abdomen, though to a less degree than on admission, and on examining his heart I note a systolic murmur, which I perceive towards the apex, and which is soft and short. He has no headache now, nor any attacks of giddiness, and his sleep is not disturbed. There is no anæsthesia nor any signs of altered æsthesia. His knee and elbow reflexes are gone.

This, gentlemen, is a very marked case of lead poisoning. The double wrist-drop, the anemia, the blue line upon the gums, the abdominal pain, tenderness, and the constipation, all make out the case, quite irrespective of the man's occupation. There are two or three points in the case which we will especially consider. In the first place, let me call your attention to the sensitiveness of the abdomen, which existed here, and yet exists to a diminished degree. This is one of the peculiar signs of lead poisoning. It is not connected with inflammation, and is most likly due to paralysis of the bowels with over-distension. It is rather relieved by deep pressure, as a rule, and is not associated with any rise of temperature; hence we cannot suppose it to be associated with peritonitis. It is a neurotic condition. There is nothing peculiar as regards the wrist-drop, except that it is double and not so marked as we might suppose from the gravity of the other symptoms. Thirdly, the absence of knee-jerk is common in these cases.

But, now, what is the meaning of this murmur which we detect in the heart? There are two suppositions which are tenable; and we must watch the case longer to see which is the more likely. It might be

an anemic murmur, or it may be the murmur of a latent mitral endocarditis—a very common result of lead poisoning. Indeed, I have been struck with the frequency with which valvular disease originates in an impregnation of the system with lead. Hence I am very suspicious in all cases of cardiac murmur associated with lead poisoning. The murmur here I think is organic.

I ground my belief that the murmur is not anemic on the fact that it is heard at the apex of the heart and is limited there. When a murmur is so limited, and does not extend to the base at all, I think we may generally correctly infer that it belongs to an organic disease of the heart, rather than to an anemic condition of the system.

Let us look at the prognosis and therapeutics of this case. The prognosis is favorable. The man will recover. What is his treatment to be? He had been placed on the iodide of potassium, which is the best eliminant of all metallic substances and especially of lead. But this had to be suspended because of the condition of the stomach. We then resorted to sulphuric acid and magnesia, the latter to keep the bowels open and the former to make an insoluble salt of lead. I would call your attention here to the value of giving small doses of sulphate of magnesia, with small doses of sulphuric acid. This is an excellent plan of treatment for obstinate constipation where there is paralysis of the bowels. Trousseau gave from ten to twenty grains of magnesia at short intervals. In this case we gave one drachm every hour until one ounce was taken, and to this treatment we added strychnine. Now, shall we continue this, or revert to the iodide of potassium? I admit, I should like to revert to the iodide. The tongue is cleaner and the stomach better, and I feel that with ten grains of potassium iodide three times a day, we can do more for the lead cachexia and more to relieve the latent heart trouble. We will, therefore, stop the sulphate of magnesia and morphia treatment, continuing the strychnine.

Delirium in Pneumonia.

I have next to show you a case in which the discussion will be rather a discussion of one of the chief symptoms than of anything else, as the case is obvious enough as regards its other features. This man is 35 years old, and was admitted on the fifth of November. He was delirious on admission and very little history could be obtained, except that he was a hard drinker. He had been in the hospital before for delirium tremens, and just before his admission this time he had been drinking very hard. About two weeks ago he was taken ill, and he was thought to have typhoid fever. Stimulants were withdrawn and he was put on milk. On admission his temperature was $102\frac{1}{5}°$, his pulse 102, his respiration 36. There was marked trembling of the tongue, which was heavily coated. His hand was tremulous and his pulse full, bounding and not dicrotic. His abdomen was tympanitic. There were no rose-colored spots. He was put on liquid diet and one-half ounce of whiskey every fourth hour. During the night he had hallucinations and illusions, but rested fairly well. On the eighth, pneumonia of the left base became manifest, and in the axilla fine crackling râles were heard at the end of inspiration. His cough was spasmodic, the sputum being rusty and small in amount, and he expectorated over everything.

Now this man has been violently delirious, and is still so, though he has improved considerably during the last forty-eight hours. His pulse during the last few days has been about 100, and has lost the fulness which it had on admission. The temperature, which was at one time high, rising even to 104°, has declined remarkably, and now ranges between 99° and 100°, resembling a crisis. Occurring simultaneously with the decline there has been a marked change in the pulmonary symptoms. There is less dulness and the râles are larger, more bronchial and less vesicular, while respiration is less frequent. There is no heart murmur, and the first sound is of only moderate strength. This man has undoubtedly a pneumonia of the left lung, but at the same time he has had delirium tremens. Whether the one came first or the other, our history does not allow us to state. The pneumonia of intemperate people is peculiar. Delirium in itself rarely occurs in pneumonia except towards the end, and even then the mind is often clear when the other symptoms are unfavorable. Early delirium in a case of pneumonia. in nine cases out of ten, suggests intemperance. I think it is very likely that here the pneumonia was really the beginning of the acute disease, after which the delirium developed. The drop in temperature bespeaks convalescence; and in this respect the pneumonia is not different from other pneumonias.

Can we get along in these cases without stimulants? My opinion is that, if we want to save the patient, we must give a certain amount of stimulus. We endeavored to do without it here for several days, but had to put the man back on it, one-half ounce every four hours; and he is improving since. By using certain remedies we may get on with less stimulants, and in my experience the best among these is cocaine, one-sixth of a grain every four hours, which gives good results. We shall continue the stimulus and cocaine in this case for a day or two, and then gradually diminish the dose. Then we shall put him on twelve grains of quinine in the day. His food is concentrated broths; and this shall also be continued.

INJURY OF THE ORBIT AND ANTRUM.—FRACTURE OF THE OUTER TABLE OF THE SKULL, WITH PENETRATION OF THE FRONTAL SINUS.—STAB OF THE CHEST.—INGROWING TOE-NAIL.[1]

BY JOHN H. PACKARD, M. D.,

VISITING SURGEON TO THE PENNSYLVANIA HOSPITAL AND TO ST. JOSEPH'S HOSPITAL, PHILADELPHIA.

Injury of the Orbit and Antrum.

Gentlemen: The first case I shall bring before you this morning, is one of injury of the head. The patient, a man sixty years old, was thrown out of a wagon a day or two ago, falling upon his head and face. You will see at once that his right eye is more prominent than his left; and you will note a peculiar thick, gummy, yellow discharge from the right nostril. The man's consciousness since his admission has been complete; although he is said to have been stunned by his fall, and he has lain perfectly quiet in bed except when spoken to. But he is able to answer questions intelligently; and it is obvious that there is no serious damage to the brain. His temperature has not risen above 100°. His right eyeball moves under his control, but not so freely or so easily as the left does. Vision in the right eye is good, but not as perfect as in the left. The conjunctiva is puffy from effusion of blood into the areolar tissue beneath it. There is much bruising of the skin around the orbit, and it is clear that, as he struck the ground, there was a projection forward of the eyeball and rupture of a vein behind it, within the orbit; hemorrhage of course ensued, and the mass of blood poured out occupies the space behind the eyeball, pressing it forward, stretching the optic nerve and hampering the action of the muscles. This clot will be gradually absorbed and the eye will return to its place.

Now, as to the discharge from the nostril. You will note that the swelling of the cheek is marked, and there is much tenderness on pressure, which also increases the flow. This liquid is merely the normal secretion of the antrum, increased by injury of the bony wall. Patients with coryza often suffer from a sense of great tension across the upper jaw, which is relieved upon the flow of just such a yellow liquid. Sometimes the discharge becomes purulent. It is not so now in this case; but possibly it will be so later. A number of cases have been reported, in which a free flow of thin, clear yellow secretion from the nostril, without apparent cause, has been found to be the initial symptom of malignant disease within the cavity of the antrum.

In this case we shall simply keep the man at rest in bed, with cold antiseptic lotions to the injured parts.

Fracture of the Skull.

The next case is also one of injury to the head. This man was admitted yesterday, having been struck in the left temple, just back of the orbit, with a piece of wood thrown off by a circular saw at which he was working. He was able to walk, with some assistance, to the hospital. On his arrival, the wound, which was bleeding freely, was examined, and found to be about one inch in length. Within it was a bit of wood not much larger than a marrow-fat pea; and it seems almost impossible that this could have been the only piece which flew off from the saw and inflicted so much injury. For, on further investigation, the bone was found to be shattered, and, after enlarging the wound in the skin, I removed a number of loose splinters, involving part of the roof of the orbit. Yet the brain case itself was not damaged, the fracture being far forward, in the portion where the orbital and cranial layers are separated by wide-meshed cancellous tissue: the outer extremity of the frontal sinus. Making this wound thoroughly

[1] Delivered at the Pennsylvania Hospital.

aseptic, we were able to predict its speedy closure without serious trouble arising. A few years ago the established rule was not to explore wounds of the head, but to wait until symptoms of grave mischief ensued. Often and often, upon the appearance of such symptoms, operative interference was resorted to, but in vain; because it was too late. Now we pursue a more truly expectant plan; we forestall the danger before it actually appears. We cannot always do this. A boy was brought into my ward two years ago, who, while operating a nail-making machine, was struck in the head with a small piece of steel. The skull was punctured at the upper and anterior part of the left side; a probe, passed through the opening, met with no resistance, and seemed to traverse the brain almost entirely across. Yet the boy had no symptoms whatever. No operation seemed to be indicated on either side of the head. He was kept in the house for ten days and was then discharged, apparently well; but in a few weeks he was readmitted with a cerebral abscess, for which trephining was performed, but without saving his life. At the autopsy a foreign body was carefully searched for, but none was found.

Stab-wound of the Chest.

The next case is that of a young colored man who was brought in last night with a stab in the side of the chest. I have just now seen him for the first time. The knife had evidently penetrated the pleura; but it was not certain whether the lung was wounded or not. Dr. Gummey very properly introduced a rubber drainage-tube; but it does not seem to be doing any good. Under antiseptic precautions, and with sterilized hands, I remove it, and you see that it was blocked up by this clot of blood, partly within it and partly around it. There is no evidence of any damage to the lung. The tube is now cleansed and re-inserted, and a fresh antiseptic dressing is applied. Whatever secretions may form in the wounded pleura will escape through the tube; and should there be occasion, the cavity may be washed out with carbolized water, with dilute peroxide of hydrogen, or with plain boiled water, as circumstances may require. If there is no effusion within the pleura, the tube will be withdrawn in a day or two and the wound will heal.

You will remember my showing you a week ago a boy about ten years old, who had been stabbed in the back, and in whom the lung was wounded. Dr. Penrose saw him in my absence, and introduced two small rubber tubes, one into the lung-wound, the other into the pleural cavity. Antiseptic dressings were used, and no suppuration ensued. On the seventh day the tubes were removed, and the wounds healed kindly.

Some of you may have heard that during the late war it was suggested by Dr. Howard, a man of some prominence as an army surgeon, that gun-shot wounds of the chest should be treated by hermetically sealing them with collodion or other materials. Cases so dealt with did occasionally turn out well; but there was no certainty about it, and the method failed to find any general favor. Had the wounds been first rendered aseptic, it may be that the verdict would have been different.

Ingrowing Nail.

The next patient, a boy fifteen years old, has an ingrowing toe-nail—a small affair, but a very painful one. Cases of this kind will not infrequently present themselves to you, but rarely in so young a person. I cannot now dwell upon the causes of this affection; but will only say that, while sometimes due to the wearing of narrow-toed shoes, it is met with also where such a condition has not existed. I believe, however, that it never has been seen in persons who habitually go barefooted. There are two elements in this disorder, or rather two lesions: a swollen and inflamed, usually ulcerated, state of the fold of skin at the edge of the nail, and a ragged and hardened margin to the nail itself. Sometimes the former exists alone, at an early stage of the trouble; but later this portion of the bed of the nail becomes inflamed, and the nail itself grows unhealthily. I always look for, and almost always find, at the deepest part of the nail-bed, back under the skin, an abscess-cavity containing a piece of dead nail-substance. Sometimes it is necessary to etherize the patient and to cut away the affected nail in its whole length and about one-third of its width, along with the underlying nail-bed. But I prefer, when it can be done, as in this case, to take a small pair of scissors, with one blunt or rounded end, and to pass this under the ragged free edge of the nail, carefully paring it away. You see I do this without causing the boy much pain. I go away back under the skin. I have now opened the cavity of which I

spoke, and here is the bit of necrosed nail-substance which was lying in it.

There is now only a smooth edge of nail. I apply a solid stick of nitrate of silver to the swollen and irritated skin, not as an alterative, but as an astringent. Now the unhealthy surface is made aseptic with sublimate solution, and dusted with iodoform, and a gauze dressing is applied.

It is not always possible—indeed it seldom is—to carry out this procedure at one sitting. Usually the patient complains of pain when the point of the scissors has been carried back some little distance; and sometimes the parts become obscured by a free flow of blood. But, by carefully renewing the attempt at intervals of two or three days, I have been able in some unpromising cases to effect my purpose, and eventually to give complete relief. Sometimes, in the class of patients met with in hospital practice, it is better to resort at once to the more heroic plan, in order to enable them to return sooner to their daily work.

COMMUNICATIONS.

MYALGIA.[1]

BY MABEL W. MOON, M. D.,
NORRISTOWN, PA.

Practitioners frequently use the term "Myalgia" as synonymous with "Muscular Rheumatism," and in many of the text-books the two words are used interchangeably, while in a few works myalgia is classed with the neuralgias. Pepper says that these affections: rheumatism, myalgia, and neuralgia, have very little in common; pain on motion being the only symptom present in them all. It is true that tenderness upon pressure exists in all; but in neuralgia it is localized over a nerve trunk or branch, while in myalgia it is generalized, extending over the whole muscle or group of muscles affected. In true rheumatism the tenderness is around the joint, and there is always pyrexia, acid sweat, highly acid urine and a decided tendency to heart complications; all of which are absent in myalgia. In the majority of instances myalgia is simply a cry for food from muscles poorly nourished and overworked. It is really not a disease, it seems to me, nor even a symptom of a disease—it is a very local affection, confining itself to a single muscle or at times to groups of them, the position and name being designated by the seat of the trouble. Thus cephalalgia or cepalodynia is a soreness of the scalp muscles, felt upon moving them, and aggravated by pressure. In not a few cases the pain is sharp when there is the slightest movement, and a dull heavy ache when at rest. Torticollis is myalgia affecting the neck muscles on the anterior and lateral aspect. This can be easily diagnosticated from the torticollis, or wry-neck, resulting from caries of the vertebræ, or due to a neuritis, as this latter is a disease of slow development, of marked chronic course, and has great tenderness over the spine. The term "cervicodynia" is sometimes applied to a myalgic affection of the posterior neck muscles. Pleurodynia, where the seat of pain is in the pectoral and intercostal muscles, may be mistaken for intercostal neuralgia upon superficial examination; but if no pain be elicited upon pressure on the three diagnostic points—at the sternum, over the spine just at the exit of the nerves, and midway between, we may be positive that there is no neuralgia present. Lumbago affecting the muscles of the back in the lumbar region, together with torticollis and pleurodynia, are the most common forms of myalgia, and in some cases are very obstinate and oft recurring. In such cases autopsies show negative muscle changes and no fixed lesion. Muscular degeneration has been found in a few instances.

From clinical observation it appears that those persons who have inherited a gouty diathesis are no more liable to suffer from myalgia than are those free from this taint. In some cases, it must be acknowledged, there exist an unknown idiosyncrasy which seems to render one individual more vulnerable to an attack than another; though the reason for this is unexplained. The most fruitful cause of myalgia is overwork: either violent exertion of muscles unused to it, or ordinary effort much prolonged. Exposure to cold, damp cold, when the person is overheated and fatigued, may precipitate an attack. Malnutrition, either of single muscles or of many, is always a forerunner of myalgia; hence persons leading sedentary lives often complain of it; loss of muscle tone being induced by lack of exercise. The "growing pains" found in rapidly-growing children are undoubtedly of a my-

[1] Read before the Montgomery County Medical Society.

algic nature. In all cases of myalgia there will be found to exist a demand for work which is not equaled by the food supply.

The onset of myalgia is generally sudden; the pain is sharp and cramp-like when the affected part is moved, comparative ease being obtained by keeping the muscles in a relaxed condition; though even then, in many patients, there may still be a feeling as if they had been pounded. The muscles are slightly full and very tender, showing some slight evidences of inflammation; but there is no fever, redness, heat or urinary changes, and the appetite remains unimpaired if the attack is of short duration.

The prognosis of myalgia is good, as far as recovery goes. The attack may last a few hours, days or weeks, and its aptitude for recurring is very marked, if the patient is subjected to the same conditions which brought on a first seizure. It has been found to take on a chronic form also.

In neurasthenic people, cod-liver oil seems to be somewhat of a prophylactic.

A brisk purge, followed by a dose of salts or citrate of magnesia is a good beginning treatment. The part should be kept at rest as much as possible and warm. In torticollis, the neck may be wrapped in hot flannel and bathed with some stimulating or anodyne liniment. The interrupted Faradic current often proves of great benefit. Massage, given by a skilled manipulator—not merely rubbing, but grasping the muscles separately and kneading them between the fingers is also useful. In omalgia, where the deltoid muscle is the seat of pain, massage seems to do but little good. The galvanic current, of a strength of from 150 to 300 milliampères, and stronger if your patient can bear it, is often of service. It should always be given in strength sufficient to cause the skin to redden, using small electrodes very well moistened, and applying them to the motor points of the muscle. One application, of fifteen or twenty minutes, following this by wrapping the shoulder in cotton, will in many cases effect a cure.

Phenacetine and salol, two and one-half grains each, in capsule, repeated every three hours, have given great satisfaction in cephalalgia. These drugs are both analgesic, and seem to answer admirably in such cases.

Pleurodynia is one of the obstinate forms of myalgia. It occurs more frequently upon the left side. Occasionally it is bilateral. The patient leans towards the affected side, and takes very shallow breaths, and holds herself—I say herself advisedly, as pleurodynia occurs much more frequently in females than in males—as every movement, cough or sneeze causes a lancinating pain, forcing cries from the sufferer. One must, of course, differentiate between pleurodynia and pleuritis or intercostal neuralgia; and it is not a difficult task in the generality of cases, to make a clear and positive diagnosis. In persons of a very nervous temperament the temperature will sometimes rise in pleurodynia, but it will quickly subside if the chest be strapped with overlapping bands of adhesive plaster, running obliquely forwards and downwards from the spinal column to the sternum. In mild cases friction with the hand moistened with a lotion consisting of one part each of laudanum and chloroform and two parts of alcohol, will answer without the adhesive strips.

When the pain of myalgia is in the limbs or gluteal muscles, a steam bath, with a good sweat induced by a Dover's powder and a hot drink, will prove beneficial. In every case a purgative, as has been stated, will be a good starting point for treatment.

Lumbago is exasperating to the patient, and in not a few cases is quite as trying to the medical attendant. The seizure is sudden. A person stooping to pick up something finds himself unable to straighten up, and when obliged to move, walks with his body bent at the hips. This is the most severe form that myalgia takes; and the patient must be kept quiet in the position which affords the most relief. Hot applications, dry or wet, are very grateful and soothing in these cases; but narcotics will often have to be resorted to. Sometimes inserting the hypodermic needle will afford a cure; and at times acupuncture acts like magic. In very stubborn cases the actual cautery may be used. Objection will doubtless be made to this by the patient, and it would be wise to broach the subject gently. Ice and salt should be applied before using the cautery, and the pain will be materially lessened. The eschar should be dressed with carbolized oil, which is both antiseptic and pain-relieving. The use of morphia is absolutely necessary at times, as the patient will weaken from loss of appetite and sleep in prolonged cases, if pain is not quieted. The ordinary hypnotics, such as sulfonal, etc., will not answer in myalgia, as a rule, though they may be tried.

Flannel should always be worn from neck

to ankles by persons subject to such attacks. It not only prevents chilling by absorbing the perspiration, but serves to keep the body at an equable temperature, thus lessening the liability of muscles that are tired or strained to become affected by cold. Iron, arsenic and strychnia are valuable tonics for cases of myalgia. Iodide of potash and syrup of hydroodic acid are also useful, from their alterative properties.

But in every case of myalgia, rest—absolute rest—is a positive necessity, in order that the muscles be allowed to regain their normal tone.

HYPERTROPHY OF THE TONSILS.[1]

BY THOS. HUNT STUCKY, M. D.,

LOUISVILLE, KY.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE HOSPITAL COLLEGE OF MEDICINE, LOUISVILLE.

Of all the diseases of the upper air passages, I know of no one more conducive to the production of serious after-effects than hypertrophy of the tonsils. As to the etiology of this hypertrophy, very little is found in current literature. The exanthemata, diphtheria, and frequent attacks of pharyngitis, seem to be etiological factors. The strumous diathesis appears to be a factor in their formation, while on the other hand we find these hypertrophies in apparently healthy children. Mackenzie states that the disease not infrequently becomes developed about the age of puberty, owing, as some suppose, to a sympathetic connection between the sexual organs and the tonsils. Sex is not without some influence in producing the affection; for out of one thousand cases recorded in Mackenzie's tables, six hundred and seventy were in males, and three hundred and twenty-seven in females. Some cases follow acute attacks of quinsy, hereditary or acquired syphilis, granular pharynx, etc.

As a rule after the age of thirty years spontaneous cure takes place, it being the natural course of the tonsil glands to atrophy after this age.

One or both tonsils may be involved, usually both. In my judgment, no improvement has been made upon the pathology, as stated in the work of Dr. Sajous (*Diseases of the Nose and Throat*, 1888, p. 286) which is as follows: "As in hypetrophy of the glandular tissues of the naso-pharynx, the lymphatic element which forms an important part in the anatomy of the tonsils is probably causative in the maintenance of the early inflammatory process which forms the primary steps to the hypertrophic changes. When this has progressed for some time, the epithelial layer is greatly thickened, and the mucosa under it is permeated with lymphatic cells and new tissue elements. The size of the tonsils is principally increased by the proliferation of new connective tissue interspersed with bundles of fibrous tissues, while their density depends upon the degree of organization which these tissues have reached."

In many cases the presence of enlarged tonsils has been unknown, until they offered a mechanical impediment to the performance of the physiological functions of the pharynx. In the young or in children, their presence often causes a diseased condition of the contiguous parts, without in themselves presenting marked symptoms. The lumen of the pharynx is diminished by their size, and thus the passage of the respired air is restricted in proportion to the extent of the hypertrophy; hence the patient keeps his mouth open and breathes through it, to compensate for the lack of current inhaled through the nose. A catarrhal condition of the nose is excited by the accumulation of secretions, due to the limited air force to dislodge and expel them. The mouth and throat are kept dry and exposed to the action of what foreign bodies may be present in the atmosphere. The voice loses its resonance; snoring and disturbed breathing, sleep and dysphagia, are complained of, while all the objective and subjective symptoms of a catarrhal inflammation of the nasal passages and throat may be present, complicated in some cases with impaired healing, through involvement of the Eustachian tubes as a result of frequent attacks of acute tonsillitis. In some cases, the lacunæ or crypts are filled with a cheesy accumulation, which evolves a very fetid odor, contaminating the breath, and the inspired air.

The interference with sense of hearing, in some cases amounting to almost complete deafness, is a frequent concomitant of hypertrophy of the tonsils. It was at one time supposed that compression of the orifices of

[1] Read before the American Rhinological Association, October, 1890.

the Eustachian tubes played the principal part in the production of throat deafness; but the observations of the late Mr. Harvey tend to prove that the increase in the size of the tonsils proceeds in the direction of the mouth, and that as the tonsils enlarge, the Eustachian aperture becomes more patent than in the normal state. He therefore attributes this form of cophosis to chronic swelling and congestion of the mucous membrane of the Eustachian tube; and recent researches have shown one of its chief causes to be pressure of Luschka's tonsil on the posterior lip of the Eustachian orifice. The effects of continued mouth breathing, which are so manifest to all the Fellows of this association, may be appropriately reiterated: "The silly expression of the face, the dilated nostrils, the nervous manner, poor articulation, frontal headache, in many cases impaired hearing, may be due to hypertrophied tonsils. By the presence of these foreign bodies, for such they are, a constant mechanical irritation is kept up."

It is immaterial whether the hypertrophy be due to the engorgement of the crypts or lacunæ due to either an active or passive congestion, or to a true inflammatory hyperplasia, the indications for treatment are cogent. The treatments of these conditions are many and varied. Where there is a simple hypertrophy, due to an acute catarrhal inflammation, the topical applications of the mild astringents have proven to me to be of little benefit. At times a patient will present himself, complaining of pain upon swallowing. An examination will reveal enlarged tonsils with active inflammation in progress. A more careful examination shows a crypt aperture, further investigation showing it to be plugged with a cheesy substance, the removal of which affords relief without treatment.

The rheumatic character of acute tonsillitis, or hypertrophy is accepted by a large number of the profession. The salicylate of soda, at the commencement of an attack, in ten-grain doses to an adult, every hour or two until one drachm has been taken, will abort many attacks. On account of the decided nausea produced in many persons by this drug, of late I have used the effervescent salicylate of lithia with equally satisfactory results and no nausea. For the simple acute hypertrophy, the treatment is constitutional and locally astringent. If, after a few applications, the size of an enlarged tonsil is not diminished, puncturing, so as to produce free bleeding, has proved serviceable. If we resorted in many of these cases to local as well as constitutional depletion, we would have fewer true fibrous hypertrophies with which to deal, and would curtail very markedly the necessity for much subsequent treatment. Chromic acid (Merck) melted on a probe and carried into the crypt, is recommended and used quite extensively. Carbolic acid has its many advocates, as has monochloral acetic acid, trichloral acetic, glacial acetic, etc. When these acids are used, a film of cotton is wrapped about the end of a small probe and carried well into the crypts. The end sought is the production of a sufficiently active new inflammatory process to cause adhesion of the sides of the pocket—enough inflammation to destroy or produce absorption of what little thickening or excessive cell production which may have occurred. Nitrate-of-silver solution instead of causing a decrease in their size, seems to cause an increase, a fact theoretically explained by the stimulation induced by the agent, and its tendency to encourage formation of new elements, as stated by Sajous. When the tonsils are soft, the galvano-cautery is very effective, a few deep cauterizations being made twice a week. I have introduced the galvanic needle its full length into the tonsils at several different points about one-eighth of an inch distant one from the other. This has proved as efficient as the method just mentioned, if not more so, causing less pain at the time of the operation, and not so much uneasiness afterwards, in deglutition.

There is one precaution which should be remembered when using local applications of acids to hypertrophied tonsils, and especially when operating with the galvano-cautery, viz.: the possibility of having an active, extensive inflammation to follow, producing middle-ear suppuration. I recall three cases which occurred in this city. One following the use of carbolic acid, the second chromic acid, and the third the galvano-cautery. The last occurred in my practice, and I now believe it was due to faulty use of the same.

The galvano-cautery snare, where we have the history of hemorrhagic diathesis, is a great and valuable addition to our armamentarium. Dr. Morell Mackenzie recommends the use of London paste, applied once or twice a week, according to circumstances, over various parts of the organ. This method is slow and painful. Where the organ is fibrous, dense and hard, tonsil-

lectomy should be resorted to. While the danger from hemorrhage is reduced to a minimum, the time, suffering and inconveniences which are overcome by ablation render it, in my judgment, the operation for speedy relief, and it should always be performed where the hypertrophy is dense in character. Where we have the opposite state of affairs, that is, softness and bogginess, the methods previously mentioned are to be preferred. By the injection of a ten per cent. solution of muriate of cocaine into the parenchyma of the tonsils, the operation by constriction of the blood-vessels is rendered almost bloodless.

The tanno-gallic gargle of Mackenzie is an excellent after-treatment for the bleeding. Hot water is also very serviceable and less disagreeable. The tonsillotome as modified by Tiemann, where a section may be made at any angle is preferred. The bistoury with forceps is recommended. This method requires an assistant and the inability to be exact in the amount removed is a serious objection. The cold wire snare is painful, slow, and will eventually be superseded by the galvano-cautery. The treatment after removal, by whatever method employed, should be constitutional and local. Most all patients suffering from tonsillar hypertrophy are anemic. With children the constructives and hematinics are indicated, the syrup ferri iodidi, syrup ferri albuminatis, and elixir of the three chlorides (iron, arsenic and mercury) being very serviceable, the latter especially during the "chlorotic" age of girls. The simpler the after-local treatment is, the better and more speedy the results.

The cause being removed, the use of a cleansing spray of melted vaseline with an astringent, stimulant or sedative, as required, will rapidly relieve. If the uvula and soft palate remain relaxed, after tonsillectomy and the use of the astringents, amputate the uvula. The ear symptoms, if acute, generally subside rapidly. After removal, special attention is called to the condition of the nasal passages. Thorough cleanliness is to be secured by the removal of all secretions. If hypertrophies of a chronic character exist over any of the turbinated processes, they should be removed by means of the cautery or in some other way. Simple distention of the Eustachian tube, by the method of Politzer or Valsalva, will oftentimes relieve the patient by a few treatments. These methods should never be used unless the nasal passages, as well as the vault of the pharynx, has been thoroughly cleansed. If there is no marked change in the tympanum, massage has proved of service. Of all the methods named, in my judgment, tonsillectomy, or ablation and the galvano-cautery are the best.

Foreign Correspondence.

BERLIN LETTER.

Opening of the Berlin University.—Glimpses of the Medical Student's Life.—Legal Protection of German Practitioners.—Suppression of Patent Medicines.

BERLIN, October 13, 1890.

The Royal University inaugurated yesterday the beginning of the new academical year by a solemn commencement held in the magnificently renovated aula. Odd procedings, as introduced hundreds of years ago, are still in vogue during that celebration. The retiring and the newly installed Rectors of the University appear attired in most gorgeous costumes, invested with the insignia of their exalted office, and are led to their seats by the janitors of the institution, who in their scarlet robes look like veritable hangmen.

The new Rector, Professor Tobler, delivered a lecture on the study of the Roman languages and announced the opening of the academical year. The strangest thing, however, connected with the affair was that not a single student was present and the uselessness of the announcement will be conceived from the fact that at present there are no students at all in Berlin. Before the 3d of December no "Musensohn" condescends to visit a lecture room, and consequently no professor is able to begin with the course.

It will interest the readers of the REPORTER, perhaps, to follow up the course pursued by the young medical student on his entrance in the University. The Rector compels him to swear to obey the laws of the University and hands him his card of matriculation. This card confers exceptional and almost undue powers upon the young man. No policeman, for instance, is entitled to arrest or touch the proprietor of the card, nor do the common courts have any jurisdiction over him. A policeman dares only demand the delivery of the card, whereupon arrest and judgment may follow, but only by

the academical authorities. Quite handy, too, is the card, for if the student desires to visit theatres, concerts, or similar places of amusement, on presenting it he either enters free or pays about one-fourth of the usual admission. If at times he should be hard up, his card proves again his best friend; for he can easily obtain money, clothes, provisions, books and almost anything at all on the strength of it. As explanation of this I will say that a student is here regarded *a priori*, as a man of honor who if unable to pay to-day, will surely do so some other time. Hundreds of legacies, in addition, administered by the University, afford poor and diligent students financial aid, and every professor is willing to wait for his fees even five years or longer. There is little or no work done during the first academical year; clubs and saloons absorbing the student's whole time. The American student does more work in three years than the German does in four. The latter may be seen parading *Unter den Linden* from 11 A. M. to 2 P. M. At two they take their lunch in the Academische Bierhalle, at a cost of twelve cents, including a glass of beer; from 3 to 5 P. M. they take their nap. At six there is a rendezvous *Unter den Linden* with members of the Club, and from 8 to 2 A. M. they are hard at work in their Stammkneipe, that is, the saloon of their Club. This is no fanciful representation, but a true description of the way in which the young German med. spends his first academical year. The second year is largely devoted to fighting, fencing and duelling; for a student does not pass for much unless his face is graced with two or more disfiguring cicatrices. In the third year he visits lectures and hospitals, and in the fourth he is spurting to make up for his prior waste of time. Examination time draws near and the necessary cramming under the "*Repetitor*" having been completed, he presents himself for examination at the first "station," which in Berlin is presided over by Jupiter Tonans, *i. e.*, Prof. Virchow. The fate awaiting him there, he knows beforehand; Virchow knows no mercy, and of one hundred candidates five only succeed at the first trial. As a rule the thunderer throws all candidates at first. Then they come up again before him in six weeks. Liebreich too is a great stumbling-block for the poor candidate. He gives you a liver and desires to know how much arsenic there is in the organ, and is a strict examiner on chemical formulas, although they do not come strictly within his province. Candidates are compelled to appear for examinations in full-dress suit, white kid gloves, and white tie. The passing of this so-called "Staatsexamen" (State examination) confers upon the successful candidate the title of "Arzt" or physician, and the right to practice, while the title of Doctor must be especially acquired. No foreign diplomas, save those of Australian Universities, are recognized in Germany.

While in this respect the German physicians enjoy great protection, legislation has on the other hand done the profession an incredible wrong. In Germany everybody has the right to practice medicine, no matter whether he knows little or nothing of the healing art. To be sure no illegal assumption of the titles "physician" and "doctor" is permitted. Hence it is not surprising to find quackery in a high state of development in Germany. Fortunately police vigilance is so strict, and punishment for malpractice is so severe, that quacks usually confine themselves to hydropathic and similar non-remedial measures. Electric and magnetic quack doctors singularly do not flourish much in Germany. Homœopathy too is very little known here. I have never yet noted the sign of an homœopathist, and they are classed without ceremony with the quacks. It is strange, however, to find that every apothecary has the sign "*allopathische und homœopathische Apotheke.*" The sale of patent medicines is strictly forbidden, and every newspaper advertising them is severely fined. The Superintendent of Police of Berlin publishes monthly in all papers an analysis of newly appearing patent medicines, states their actual cost, emphasizes their uselessness or possible injurious character, and warns against their purchase. Only recently H. H. Warner's Safe Kidney Cure was thus proscribed by the authorities. It is clear that under these circumstances venders of patent medicines cannot become millionaires as in America.

—In a late number of *La Lyon Médicale*, attention is drawn to an article by Dr. Filatoff, of Moscow, showing that heliotrope can be substituted with advantage for quinine. The plant, it is stated, has for some time been in use as a popular remedy against fevers in Russia, in Turkey, and in Persia. In each of these countries a tincture is prepared by macerating in alcohol the leaves and stalks of the plant.

PERISCOPE.

Curability of Acute Phthisis.

Dr. McCall Anderson, Professor of Clinical Medicine in the University of Glasgow, says in the *British Medical Journal*, November 8, 1890:

The term acute phthisis is frequently used in a very vague manner, and is applied to cases which have no title whatever to the appellation, as any one can readily satisfy himself by a perusal of the medical journals. It is, therefore, important at the outset that I should specify the limited class of cases to which I am about to refer. By acute phthisis, then, I do not mean cases merely of short duration, nor chronic phthisis associated with more or less fever, nor those which, while running their course, suddenly develop acute symptoms. But I allude to cases of phthisis setting in suddenly, with high and continuous fever, great prostration and profound involvement of the system, reminding one rather of typhus or a severe attack of typhoid fever than of a pulmonary affection. Indeed, in some instances it may be necessary to watch the course of the disease for some days before an absolute diagnosis can be made, so that the term "galloping consumption," used by many of our leading authorities, although not a scientific one, conveys to the mind a most accurate impression of the kind of disease with which we are dealing.

Such cases are comparatively rare, and are only exceptionally met with in hospital practice; not only on this account, but because the patients are supposed to be too ill to be removed, or, if removed, they are fully as likely to find their way into a fever as into a general hospital.

There are two forms of acute phthisis: (*a*) acute tuberculosis, and (*b*) acute pneumonic phthisis. In acute tuberculosis tubercles are more or less copiously disseminated throughout the lungs, and often also in other organs. But the symptoms of acute phthisis do not appear unless or until these foreign bodies produce congestion or inflammation of the pulmonary tissues, and, if the patient lives long enough, breaking down of the lung tissue may occur here and there, with the development of small excavations. That the infiltration of the lung with tubercles does not necessarily lead to acute phthisis is proved by the occasional discovery, *post mortem*, of obsolete tubercles scattered through the lungs in the case of those who never experienced pulmonary symptoms during life.

In acute pneumonic phthisis the disease exhibits almost from the first a more or less extensive consolidation, most frequently of the upper lobes, which often spreads to other parts, and, instead of resolving in a week, like a croupous pneumonia, leads to rapid and widespread destruction of lung tissue, which soon terminates the life of the patient.

A perusal of the literature of the subject leads to the conviction that authorities are very hopeless with regard to the prospects of sufferers from this disease, and, while I have read numerous records of fatal cases, I have never met with a carefully recorded case fulfilling the definition of acute phthisis, as I understand it, in which a complete restoration to health occurred. There are many, however, who hold that acute tuberculosis is the more certainly fatal of the two, while I am rather inclined to the opinion that acute pneumonic phthisis is probably the more dangerous, as it leads to such rapid and widespread destruction of the pulmonary tissue. Including the case which follows, I have put on record seven instances of acute phthisis, all of them treated in a similar manner; and it is a remarkable fact that of the seven, five recovered. Of the two fatal cases, one was beyond the reach of recovery when he came under observation, his lungs being extensively disorganized, while in the other instance the fatal issue was due to the complication of perforation of the lung. There is an interest, however, in connection with the fatal cases in reference to diagnosis, for in both the *post-mortem* examinations showed their tubercular nature. The cases to which I have just alluded—of which four were published in the *Lancet*, March 24 and March 31, 1877, and the fifth and sixth in the *British Medical Journal*, February 19, 1881, the seventh being described later on—tend to show that if acute phthisis is grappled with early and energetically, and *with an expectation of success*, the prognosis is far from gloomy, and the more I see of the disease the more hopeful do I become.

Let me give you a brief outline of the kind of treatment upon which, in my opinion, reliance may be placed, but it must be understood that no two cases can be treated exactly in the same way; each patient and his surroundings must be specially studied before deciding upon our line of action. The principal indications are—1, to keep up

the strength; 2, to keep down the fever; and 3, to treat any special symptom or complication which may arise.

Two thoroughly trained and reliable nurses are indispensable, one for day and the other for night duty; for without admirable nursing no hope of improvement can be entertained; and the hygienic and other surroundings of the patient should be satisfactory, so that we need not be surprised that, when the disease occurs in the homes of the working classes, it is almost necessarily fatal, and that hospital patients have the best chance of recovery. The patient must be fed constantly on fluid food (soup being avoided if diarrhœa is present) both day and night, and stimulants (from f℥ ii to f℥ x) are required early in the attack, but should be given in small quantities, frequently repeated and along with the food. In fact, the dietetic treatment should correspond with that of a case of fever presenting symptoms of a similar degree of severity. At bedtime a subcutaneous injection of sulphate of atropine (gr. $\frac{1}{100}$ to gr. $\frac{1}{60}$) is given. This checks perspiration when present, acts as a sedative to the system, indirectly helps to reduce fever and diminishes the secretion from the lungs.

Remedies are given with the view of lowering the temperature. This is a point of the utmost consequence, because the majority of the patients die consumed by the fever. Some benefit is derived by allowing the sufferer to suck ice freely, by giving the food and drinks iced, by sponging the body with iced vinegar and water, or even by using iced enemata.

But our main reliance is upon one or more of the following methods:

1. Niemeyer's antipyretic pill or powder every four hours, containing gr. 1 quinine, gr. ½ to gr. 1 digitalis, and gr. ¼ to gr. ½ opium. The proportion of opium may even have to be increased beyond this if there is much diarrhœa. The effect of the digitalis must be carefully watched, and it must be omitted for a time if the pulse becomes preternaturally slow and irregular and the secretion of urine very scanty.

2. The administration daily—particularly shortly before the temperature tends to be highest—of from 10 to 30 grains of quinine, given, as suggested by Liebermeister, either in a single dose or, at all events, within an hour.

3. The application of iced cloths to the abdomen for half an hour every two hours so long as the temperature exceeds 100°. The application of iced cloths is made in this way:

The night-dress is pulled well up over the chest so as to avoid any possibility of its being wet, and, for a similar reason, a folded blanket is placed across the bed under the patient's body. The usual bedclothes are arranged so that they reach up to the lower part of the chest only, which latter is covered by a separate blanket in order to prevent unnecessary exposure while the cloths are being changed. Two pieces of flannel are employed, each being sufficiently large when folded into four layers to cover the whole of the front and sides of the abdomen. One of these, wrung out of iced water and covered with a piece of dry flannel to protect the bed-clothes, is applied, while the other is lying in a tub of iced water at the side of the bed. The pieces of flannel are changed every minute, or so often that they still feel cold when they are removed. The changing of the flannel, particularly when two persons are in attendance, one to remove the bed-clothes and the flannel, the other to apply the piece which is freshly iced, can be accomplished in a few seconds.

I mention these apparently trivial details because I often see the process carried out in such a way as to be worse than useless, and because I have frequently been interrogated on the subject. But I think it right to add that I do not wish to lay too much stress upon the value of iced cloths by themselves, but to attribute the success of the treatment to the combination of measures employed. Of course the same precautions must be taken in using iced cloths as in the employment of the cold bath, and they must be removed at once if the temperature falls to near the normal, and if there is any tendency to coldness and collapse.

Such is a general outline of the line of treatment from which such excellent results have been obtained, and the more experience I have of it, the more confidence do I place in it; but, of course, in this, as in all disease, we must avoid routine, and must study each case by itself, as no two cases can be treated exactly alike.

New Antiseptic Dressing.

Dr. Francis T. Heuston, in a paper read in the Section of Surgery at the annual meeting of the British Medical Society,

Birmingham, July, 1890, said that some months ago Dr. Tichborne, whose work in the chemical world is so well known, suggested certain drugs which he considered would probably meet his requirements. After due consideration Dr. Heuston experimented with those which he thought would be most effectual, chiefly napthalin and sulphite of zinc; the latter proved so successful in his hands that he brings the result before the profession in the hopes that it will be found of service. He claims for the dressings prepared with this salt that they are non-poisonous, non-irritative, and highly antiseptic, while their application is extremely simple.

In applying the dressing Dr. Heuston sometimes dips the piece of gauze placed in contact with the wound in a weak carbolic solution—this is not, however, essential—and then applies three or four layers of dry sulphite of zinc gauze, the whole being retained in its position by a simple gauze bandage. As will be seen, it is applied in the manner commonly employed in the use of alembroth gauze.

As far back as 1870 Dr. Tichborne introduced sulphite of zinc to the profession as an antiseptic. At that time this salt was not in commerce, and the few existing references which were to be found in such books as Gmelin's *Handbook* or Watt's *Dictionary of Chemistry*, were anything but correct. In the paper above referred to, its properties were described, as also a new process for its preparation, and its use as a general antiseptic suggested; but in 1870 antiseptic surgery, as now understood, did not exist, and it is now proposed to utilize this salt to prepare an antiseptic gauze having special properties. Dr. Heuston gives the result of a carefully conducted series of hospital experiments to which he has submitted it, and which seem to conclusively prove its great value as an adjunct in operative surgery. He says:

"In the original paper read before the British Pharmaceutical Conference, 1870, the chemistry of this salt and the process of making it were dwelt upon very fully; for the purposes of this paper it will, therefore, be only necessary to give concisely a few of the salient points which bear upon the inquiry.

"Sulphite of zinc is best prepared by mixing in solution six parts of zinc sulphate and five and a quarter parts of sodium sulphite. The new salt forms slowly, and falls as a white crystalline precipitate; it is very insoluble in water, but soluble in an excess of sulphurous acid.

"Sulphite of zinc exists in two conditions of hydration as a di or trihydrate according to the temperature at which it is dried, as we will assume that in making the gauze and similar fabrics the salt is always dried at 100° C., the composition of the sulphite present will be $ZnSO_3 2H_2O$. When dry, sulphite of zinc is a perfectly stable compound, and we have gauze six months old which possesses all its pristine antiseptic properties. We tinge the gauze with an organic dye, and this fact affords an easy method of determining if the gauze, however old it may be, possesses its antiseptic properties. If a little gauze is placed in water and acidulated with sulphuric acid, it at once bleaches from the free sulphurous acid, when wet or in solution it suffers a slow oxidation, and hence its antiseptic power. It is very insoluble in water, being only soluble in that menstruum to the extent of 0.16 per cent. (about ¾ grain to the ounce). When such a saturated solution was tested from day to day with a volumetric solution of iodine, its oxidation into sulphate was seen to be very gradual, but very regular.

"On the eighteenth day, the sulphurous acid was all converted into sulphuric acid. When sulphite of sodium is mixed with sulphate of zinc, the sulphite of zinc is very slowly formed, but is ultimately all deposited, owing to the insoluble nature of the newformed salt. This phenomenon adapts it naturally and with ease to the permanent saturation of any fabric, as gauze or lint, and without the intervention of any adhesive material such as starch. We first boil the gauze in water to thoroughly wash and sterilize it; then upon this gauze is poured a boiling solution of zinc sulphate and sodium sulphite in equivalent proportions; when thoroughly mixed and saturated the whole is allowed to stand twelve hours. The zinc sulphite is deposited in and around the fibres of the fabric in microscopic crystals, but soft and even unctious to the feel. The deposition of the zinc sulphite is represented by the subjoined equation:—

$$Zn\ SO_4 + Na\ SO_3 = Zn\ SO_3 + Na\ SO_4.$$

"Now, it will be noticed that sodium sulphate is a resultant of the above decomposition; the greater part, however, remains in solution, and we pass the gauze twice under rollers submerged in water with the object

of removing all traces of this sodium sulphate which might remain. The gauze may be dyed, with the twofold object of watching the progress of the discharges, and with the purpose of branding it distinct from other surgical dressings."

In the discussion, Mr. Kendal Franks said he had found so much cutaneous irritation following the use of the mercuro-cyanide gauze that he was glad to put to the test of experience the gauze dressing described by Mr. Heuston. He had been very fairly satisfied with the alembroth gauze, though it also occasioned irritation of the skin. He has now used the sulphite of zinc gauze in many cases. In every case he has found the wound to run a perfectly aseptic course, and in no case has he seen the slightest irritation of the skin beneath the gauze. It would, he thought, prove a valuable addition to surgical dressings.

Sure Cure for Phthisis.

The Paris correspondent of the *Lancet*, Nov. 8, 1890, writes:

M. and Madame Foux are an old couple of about seventy years who have discovered an "infallible cure for phthisis." M. Foux exercises the calling of engraver, but, devoting his leisure hours to scientific research, he succeeded, aided by his spouse, in inventing a potion "*fondant, détensif,* and *cicarisant,*" which plays havoc with the tubercle bacillus and immediately restores the patient to health, even in desperate cases. The couple enjoyed an immense reputation in the east end of Paris, and numbers of people came from all quarters to purchase a few drops of the precious elixir, which has quite forestalled the rather late-in-the-day remedy which Koch, of Berlin, is at so much pains to make public. M. Foux differs from this investigator, however, in that, in order to preserve in perpetuity the secret of his labor, he always administers it in person, or, failing this, he deputes the trusty partner of his joys and fame to act for him. When the patient has swallowed the draught Foux retires, carefully pocketing his fee, but he never leaves a drop of the remedy in the hands of the sick person. On a recent occasion he was summoned to the bedside of a poor fellow in the last stage of consumption; but, having other and more pressing professional engagements, he sent his wife with the draught. She administered it, but scarcely had she gone than the patient was seized with severe hemoptysis. Now with this untoward crisis the harmless decoction had in all probability nothing whatever to do; but such is the fickleness and ingratitude of human nature that the friends attributed the hemorrhage to the medicine. The nearest chemist was now summoned, who in turn called in a doctor. Having attended to the patient's immediate wants, they decided to summon the philanthropic lady to exhibit another potion, but set a trap to confiscate it before she could do so. For this purpose the chemist concealed himself in the room, and appeared just as the draught was about to be swallowed by the patient. Having seized the phial, he commanded the old lady to accompany him to his shop. Once arrived there, he put the bottle down for a moment, at the same time threatening the quack's wife with the consequences of poisoning people. Seeing an opportunity, she snatched the phial and swallowed its contents, retorting on the baffled chemist that she was a strange poisoner, since she drank her own poisons. When brought before a police magistrate a few days later, the male quack declared with the most haughty dignity that nothing in the world would induce him to reveal his secret. The female prisoner gave an amusing account of the trap that had been laid for her, declaring that were it not for her presence of mind, not only would the secret have been discovered, but that the infamous chemist would not have scrupled to add some poison of his own to her drug. She naively declared, however, that she could give no better proof that the medicine was harmless than by swallowing it herself, and she caused considerable hilarity by calling the magistrate's attention to the fact that she was not yet dead. In the result they were fined $200.

Carbonic-acid Gas for Gonorrhœa.

Dr. Thomas C. Minor, of Cincinnati, in the *Cincinnati Lancet-Clinic*, November 22, 1890, proposes the treatment of gonorrhœa and gleet with carbonic-acid gas water, and seems satisfied with the results he has obtained in a few cases by this method. After describing his first case he says:

"During the summer of 1888 at least three other cases were treated in the same manner, with varying results as to the duration of treatment, and in all these cases the

marked effects of checking discharge and allaying urethral irritation were manifest. One of these cases recovered in five days, but in the other two cases the disease persisted for at least two weeks before it disappeared. In these cases, as in the first, the supra-pubic pain was intense. Further experimentation was discontinued until the winter of 1889, when two more cases were treated in a similar manner; also a case of gleet of eight months' standing. The former cases yielded to treatment, one in five days and the other in about two weeks. In the case of gleet almost three weeks' time was consumed before the patient was perfectly well. During the present year (1890) two cases of acute gonorrhœa were most satisfactorily treated, one yielding in six days and the other in two weeks.

"The supra-pubic pain following the injections has been noticeable in all of these cases, and is the only objection offered to the application of the treatment; in fact, in several cases, when attempts were made to apply the remedy a second time, the patients objected so strenuously that the treatment was not pursued further.

"The advantages of this plan of treatment may be briefly enumerated:

"1. Its ready adaptability. A patient, after having the method used once or twice, can apply the treatment himself.

"2. The speedy diminution in the amount and character of the discharge. The amount of discharge is usually lessened at least one-half by the second day of treatment; it loses its purulent character, becoming thin and watery.

"3. The advantage of an entirely local treatment, without change of diet. No nauseous drugs like copaiba and sandal wood are given to upset the stomach, and in two instances where the patients took a few glasses of beer daily no change was made in food or drink, although those patients who did not take stimulants yielded most rapidly to treatment.

"Care should be taken when the supra-pubic pain comes on to immediately relieve the tension in the urethra and allow the seltzer or vichy to flow from the urinary passage. In cases where not very intense pain results the gas may be allowed to have full play on the mucous membrane for four or even five minutes.

"Several medical friends in this city are now experimenting with this, so far as the writer is aware, new plan of treatment, with varying results. Dr. W., who will probably report some cases before one of the societies, at my suggestion used the carbonic-gas water, warmed, for vaginal irrigation in several cases of leucorrhœa with surprisingly good results; also in a case of cystitis, where the results were more than usually beneficial.

"As the treatment is so simple, it merits a trial at the hands of careful practitioners. The apparatus is not complicated, being only a charged syphon with a rubber tube armed at the urethral end with either a champagne tap or a female catheter; thus any one can easily make the therapeutic application. It has seemed to the writer that in cases of stricture a catheter could be connected with the gas-containing tube and the pressure of the gaseous water from the syphon be made to distend the urethra directly in front of the instrument, thus avoiding unnecessary laceration and hemorrhages.

"In making these irrigations it is well to remember that the patient should void his urine before the injection is used."

Induction of Premature Labor.

At the Tenth International Congress, the Gynecological Section discussed the indications and methods for the induction of premature labor. The correspondent of the *Medical Press*, October 8, 1890, writes that the discussion was introduced by Dr. Calderini, of Parma, who commenced with the statement that in the interest of the child premature labor should not be induced when the pelvis was ricketty, and the conjugate below 7½ ctm. (2 15-16 in.). With proper antiseptic precautions, on the other hand, when the pelvis was contracted, non-ricketty, when the conjugate was 8½ ctm. (3 1-16) or even less, premature labor could be induced with advantage. The mortality of children born after prematurely induced labor might be diminished. The best method of inducing it was by warm douching through a Fergusson's speculum, and the introduction of a solid bougie up to the fundus uteri. In certain diseases it was advantageous to puncture the membranes simultaneously. Dr. Calderini brought forward a table showing the comparative maternal mortality with the different methods of procedure, viz.: an ascending mortality from turning, induction of premature labor, symphysiotomy, forceps, perforation, Porro's operation and Saenger's Cæsarean section. The child mortality on the other hand ascended from

Saenger, to Porro, symphysiotomy, forceps, artificial induction of labor and turning. In pelves of over 7.5 ctm. induction of artificial labor was to be preferred, and at the end of term combined version. In the interests of the child the preference might be given to Cæsarean section, but the maternal mortality from the operation was still too high to permit of its displacing induction of premature labor, turning and forceps.

Prof. Dohrn, of Königsberg, was of opinion that induction of premature labor was the most appropriate method of delivery when the pelvic narrowing was moderate—conjugate 7 to 8 ctm. He could give recent statistics of 271 cases in proof of this; 271 inductions of premature labor gave 163 living children, or 66.1 per cent., whilst 171 full-time labors of the same women gave 50 living children, or only 29.3 per cent. As regarded the mothers the results were: 318 inductions of premature labor, 16 deaths, equal to 5 per cent. Cæsarean section could not yet take the place of induction of premature labor. Diameters of 7 to 8 ctm. were the lowest limit of artificial induction. The most careful antisepsis was necessary. He warned his hearers against operative delivery of the induction of premature labor.

Prof. Leopold, of Dresden, had induced premature labor in 75 cases with one death, but his maternal mortality after Cæsarean section was 9 per cent. He said the indication for artificial premature labor began where that for Cæsarean section ceased, it could only come into consideration in pelvis of 7 ctm. (2¾ in.) and over. The mortality of children was great from the difficulty of correctly estimating the period of pregnancy, labor was often induced too early. Cæsarean section was an operation for hospitals, not for private practice. At the end of pregnancy, perforation was preferable to Cæsarean section, and with a later conception the timely induction of premature labor.

Prof. Löhlein, of Giessen, did not believe that induction of premature labor and Cæsarean section could come into rivalry, but perforation of the living child and Cæsarean section. Labor should not be artificially induced before the thirty-fifth week. It was indicated in cases of nephritis. One should be cautious about inducing labor in cardiac disease.

Herr Fehling, of Basle, in 70 cases of induced premature labor had had one death, and 80 per cent. of living children. He was therefore in favor of inducing labor. As regarded the methods, he first used iodoform gauze tamponnade, then the colpeurynter, then again the tamponnade; and if these means failed, he allowed the colpeurynter to remain in.

Herr Balandin, of St. Petersburg, pointed out that the main action of means of exciting pains in artificially induced premature labor, depended on septic influences. He preferred induction of premature labor. It was often complicated by feeble pains. A firmly distended uterus responded more readily than a flabby one. Generally speaking the induction of premature labor was free from danger.

Herr Kocks, of Bonn, recommended an instrument devised by himself for the purpose, which dilated vagina and cervix uteri both at the same time.

Mouth of the Infant at Birth.

The *Edinburgh Medical Journal*, November, 1890, contains a paper of unusual interest by Dr. J. W. Ballantyne, upon the anatomy of the head of new-born infants, in which he gives the following description of the oral cavity.

"In all the sections of the heads of infants which I have made, the mouth was seen as a potential cavity, the dorsum linguæ came into contact with the vault of the palate above, and the tongue was in apposition to the inside of the cheeks and gums laterally. In all the specimens, also, the tip of the tongue lay upon the upper surface of the lower gums. It is a fact worthy of note, that even when the mouth is tightly closed the gums do not come into contact. This fact, which is revealed by frozen sections, Symington specially dwells upon as showing that provision exists at birth for a considerable development of the alveolar arches and teeth before the gums of the two jaws can really meet. I have not, however, been able in my cases to show that the distance between the jaws is so great as Symington found it, namely 6 mms., for in the specimens examined it measured from 2 to 4 mms., and in one case the jaws were in contact. Another peculiarity about the buccal cavity in the new-born infant is the fact that the lower jaw lies in a plane posterior to that of the upper jaw. In a sagittal vertical section of the head, the anterior surface of the lower jaw is seen to lie in the same vertical plane as the posterior surface

of the upper jaw. As life advances the jaws come into line with each other, and with the development of the teeth the space between the gums disappears.

"If the tip of the tongue be raised in the case of the new-born infant, two folds of the mucous membrane are seen, one of which, the larger and outer, has a dentated margin, and is called the plica fimbriata; the other, which is smaller and is situated nearer to the middle line and the frenum, is known as the plica sublingualis. In one of my cases there was found under the tongue on the right side a congenital ranula which contained a small quantity of clear limpid fluid.

"H. Ranke has in a recent paper (Ein Saugpolster in der menschlichen Backe, *Virch. Arch.*, Bd. xcvii, pp. 527–547) drawn special attention to pads of adipose tissue which exist in the cheeks of new-born infants, and which are, as Symington shows, present also in the child. Ranke was led to the study of these bodies by the fact that in a child one year old, in a state of great emaciation from continued diarrhœa, the cheeks presented a swollen appearance. This swelling he found to be due to the presence of a distinctly encapsulated mass of adipose tissue, the so-called sucking pad (Saugpolster). He made sections of the face, coronal and horizontal, in the new-born infant, and also dissections from the skin surface inwards, and found that these pads were distinct structures which were not continuous with the subcutaneous adipose tissue. In several of my sections the relations of these pads could be seen, and they were always easily differentiated from the surrounding fat from the fact that on putting the sections into spirit the pads changed their color slightly, and shrank from the adjacent tissues in one case to the extent of being easily removable. Each pad lies in the neighborhood of the duct of the parotid gland, upon the buccinator and partly upon the masseter muscle, and has superficial to it the musculus risorius of Santorini. An offshoot from the pad passes into the spheno-palatine and zygomatic fossæ. Each has a vertical diameter of about 2 ctms., a transverse of about 1.5 ctm., and an antero-posterior of a little over 1 ctm. They are found not only in the infant but also in the child and adult, and are present even when the adipose tissue in other parts of the body is extremely small in amount. They are no doubt connected physiologically with the act of sucking, hence the name of sucking cushion given to them, and probably act by distributing equally the atmospheric pressure, and preventing the drawing inwards of the buccinator muscle between the gums during the efforts of suction when a vacuum is created in the buccal cavity."

Medical Training and the Languages.

In a recent address before one of the largest medical associations in the United States, the speaker argued that the medical student's work should begin with his academic life; that the selection of a career in medicine being determined upon, attention should be given to the cultivation of the mind in the study of Latin, Greek, German, French, physics, etc., to the exclusion of the higher mathematics. Every one admits that a knowledge of Latin is essential to intelligent medical training, and when one is reminded that practically one-half the words in Dunglison's *Medical Dictionary* are of Greek origin, it is not difficult to become convinced that this *dead* language is equally essential. As far as medicine is concerned, nothing can be more deplorable than the decline of Greek in the classical curriculum. In Hungary, according to a recent letter in the New York *Times*, it has been abolished, while in Italy it is treated as an optional aid to philology. The importance of German and French may be appreciated when it is estimated that about one-half of current medical literature appears in these languages.—*Harper's Weekly.*

Santoninoxime as a Vermifuge.

The *Journal de Médicine*, November 9, 1890, says that santoninoxime, according to the *Répertoire de Pharmacie*, 1890, is obtained by heating five parts of santonin with four parts of chlorhydrate of hydroxylamine and from three to four parts of chalk, in the presence of alcohol. The product is eighty for each one hundred parts by weight of santonin employed. The substance consists of silky needle-like crystals, white, insoluble in cold water, sparingly soluble in boiling water, soluble in alcohol and acetic acid. The crystals melt at 216° C. (420° Fahr.), and rotates polarized light to the left. It has been praised as a vermifuge, and may be used instead of santonin. It can be administered in doses two or three times larger than the latter substance without causing accident.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

DISTURBANCES OF EJACULATION.

Affections of the male sexual organs, which involve, or appear to involve, the generating power of the patient, are frequently extremely difficult to treat. The cause of this is perhaps oftener to be sought in the patient himself than in the local disorder; in other words, the trouble is with the mind and general nervous system rather than with the sexual apparatus. If a man gets an idea that, as the result of spermatorrhœa, or gleet, or premature ejaculation, or some other disorder, he is impotent or sterile, it requires all the authority and tact of a wise physician to accomplish much towards his restoration to health. Confidence in the attending physician is all important. If the patient can be brought to leave the thinking about his case to be done by his physician, and get rid of his morbid self-contemplation, half the battle is won.

Quacks and physicians with more reputation than character have done much to exaggerate the significance of sexual disorders, and even those who can have no object in deceiving have spoken with unwarranted positiveness in regard to these matters. Thus Alfons Hanc, of Vienna, in an article published in the *Allg. Wiener med. Zeitung*, No. 29, 1890, declares that "a well-timed successful ejaculation of human semen is without doubt the most essential element of the act of copulation, and is almost as a rule a *conditio sine qua non* of the generating power in man." As regards the latter part of this statement, it should be remembered that the spermatozoa alone are the essential elements, so far as the man is concerned, of fecundation. These retain their motion for at least twelve hours outside the body, when the semen is kept in a test-tube, and in all probability live for several days in the secretions of a healthy vagina. There is some reason to believe, it is true, that at the height of the sexual orgasm the mouth of the womb opens, and perhaps even at such times the semen is sucked up into the womb. But the normal os that will admit a sound will certainly admit active spermatozoa at any time, and if so, what is to prevent the fecundation of an egg, if one is present? The statement of Hanc is too sweeping, and needs qualification. Coitus with ejaculation at the height of the orgasm is possible to sterile men, that is to say, men whose semen contains no spermatozoa, or only dead ones; and, on the other hand, men with varying degrees of impotence, but with living spermatozoa in their semen, are capable of begetting children.

It is quite true that perfect coitus implies successful ejaculation at the proper time, but it does not follow that without it there can, as a rule, be no fecundation. There are unquestionably distinct departures from normal ejaculation: it may occur too

soon or too late; it may occur very slowly and in drops, instead of in a jet; or it may be absent altogether. Ejaculation may be complete but be painful, or free from pleasurable sensation. Disturbance may arise also from the effect of alcohol or nicotine. But it is a great mistake to believe that these abnormalities necessarily preclude paternity. Moreover, our own belief will be reflected in the treatment of patients. Probably the most frequent abnormality of ejaculation is marked by precipitancy. There is an erection, more or less complete, and sexual desire, but before the act of coitus is completed, and sometimes before intromission of the penis, ejaculation occurs and the penis becomes flaccid. Such patients have a hypersensitive prostatic urethra, with relaxation and perhaps dilatation of the orifices of the ejaculatory ducts. They require local and systemic treatment, a considerable degree of continence, and afterwards the assurance that if they proceed with greater deliberation and less excitement and without previous dallying, coitus will be performed much more satisfactorily. If their semen contains normal living spermatozoa, they can be told with safety that there is no reason on their part why conception cannot occur. If, on the contrary, we believe that perfect coitus is almost essential to fecundation, we shall grapple with the affections in question with much less hopefulness, and the degree of hope and confidence with which we can inspire the patient will be far less. The consequence will be lack of success in treatment.

FUGU POISON.

The nature and effects of the poison of the Japanese fish, the fugu (pronounced *fungu*), have been generally overlooked by modern toxicologists, and it is only recently that they have received careful scientific study. A report of the investigations of Drs. Takahashi and Inoko, regarding fugu poison, appears in the *Deutsche Medicinal Zeitung*, July 3, 1890.

The fugu is a species of tetrodon. It is a scaleless fish, averaging about a foot in length; with a short head, a thick, round body and a spotted back. It is found principally on the west coast of Japan. Regarding the poison, Drs. Takahashi and Inoko have found that it lowers the respiration and causes its cessation, without giving rise to convulsions. In mammals the heart is not directly affected, and continues to beat for some time after the respiration has ceased. The pulse is gradually slowed; the blood pressure is lowered, and the vaso-motor centre is paralyzed, but not the peripheral vascular nerves. The cardiac inhibitory action of the vagus is at first lessened, and finally is lost. The respiratory centre is paralyzed, and convulsions cannot occur. The excitability of the peripheral motor nerve ends decreases, in mammals, and can be entirely lost in frogs. In frogs the spinal cord is paralyzed. The cause of death is evidently paralysis of the respiratory and vascular nerve centres. The effect of fugu poison upon the motor nerves is similar to that produced by curare, but the fugu poison differs from the latter in that it paralyzes also other nerve centres in the medulla oblongata.

The fugu poison is contained in the living fish, and is therefore not a product of decomposition. The poison produces no toxic effects upon fishes of the same species. Drs. Takahashi and Inoko do not state in what part of fish the poison is found. According to the belief of the Japanese fishermen the meat of the fish is entirely innoxious, the poison being contained only in the liver and gall-bladder. If these organs be removed without being broken, and without the contents of the gall-bladder coming in contact with the meat, the fish may be eaten with impunity. It is considered to have a most delicate flavor; and as many fishermen persist in eating the fish in spite of the risk, cases of poisoning are not infrequently met with. The poison is considered to be always fatal in its effects. It is soluble in

water, but very slightly so in alcohol; and it is insoluble in ether, chloroform, benzine or amyl-alcohol. It is not precipitated by acetate of lead or by any alkaloid reagents. The poison is differentiable and not changed by boiling for a short time.

From these facts the investigators conclude that fugu poison is neither a ferment, an albuminoid nor an organic base. Its chemical composition is still under investigation. Personal experience with a fatal case of fugu poisoning confirms the assertions of Takahashi and Inoko regarding the symptoms of poisoning. The case in question was that of a strong fisherman, about thirty years old. An hour before he had eaten fugu, which was supposed to have been well cleaned. When seen, he was lying upon the beach in a semi-conscious condition. The pulse was slow but strong. Respiration was greatly embarrassed; breath was taken with great difficulty and in gasps. The chest heaved violently, and the man was in a cold perspiration. Such restoratives which were at hand were resorted to, and an attempt to induce vomiting made, but in vain. Within half an hour the man was dead.

AN INSTRUCTOR IN ABORTION.

From points in the United States a thousand miles apart the Editor of the REPORTER has had sent to him, with the suggestion that it be made the subject of comment in these columns, a pamphlet, which has every appearance of deserving the severest censure. The author of the pamphlet is one whose business it is probably not best to advertise by giving his name. His pamphlet offers for sale a translation of a book by Velpeau, in which, as he states with well-chosen expressions, instructions may be found how to produce abortion in a variety of ways, some of which are "not known to the medical world," and also "valuable hints as to the best means by which evasion of the law can be accomplished when a physician is so unfortunate as to be 'suspected' of having been guilty of this step." He also says: "I don't know that the author intended it for a lesson when he explained how abortionists scientifically bleed their patients; be that as it may, he certainly lays bare the road to a fortune for any one desiring to follow this questionable practice."

Our correspondents evidently think this pamphlet a cunningly-devised scheme for securing purchasers of a book of instruction in a practice scorned by decent men and condemned by moral men both in and out of the medical profession. This opinion seems reasonable to us; and we hope, if the seller of it be the scoundrel that he may be suspected of being, that a way may be found to bring him to justice.

At any rate, we are glad to have evidence that readers of the REPORTER turn to it for sympathy and assistance in exposing wrongdoing; and we assure them that they will always have both. An experience of nearly four years has demonstrated the fact that infallibility does not fall upon one's shoulders with the editorial mantle; but an honest purpose to do right and to hate evil every one may hope to have—and hope also that it will make up for some errors of judgment.

A PHILADELPHIAN'S DEATH UNDER THE KOCH TREATMENT.

Rudolph Long, about 25 years old, of 2637 North Ninth street, this city, recently went to Berlin to place himself under Prof. Koch's treatment for the cure of consumption. On Monday morning, December 15, the family received a letter from their son telling them that he had succeeded in obtaining admission into the hospital and was receiving treatment. On December 16 we received information that the man had died on December 14.

As far as we know this is the only patient who went to Berlin from this city for Koch's treatment. The case was not an advanced one of tuberculosis, although the symptoms were well marked.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

EPILEPSY: ITS PATHOLOGY AND TREATMENT. By Hobart Amory Hare, M. D., B. Sc., Clinical Professor of the Diseases of Children and Demonstrator of Therapeutics in the University of Pennsylvania, etc. Small 8vo, pp. 228. Philadelphia and London: F. A. Davis, 1890. Price, $1.25.

This volume is No. 7 in the Physicians' and Students' Ready Reference Series, and is the essay for which a prize of four thousand francs was awarded to Dr. Hare by the Royal Academy of Medicine of Belgium, December 31, 1889.

The author records and appears to adopt the view developed especially by Hughlings-Jackson, Ferrier and Horsley, that epilepsy arises from a disturbance in the cerebral cortex. As to treatment, the book reports nothing new, so far as the use of medicines is concerned. Dr. Hare thinks the bromides the best general remedies, but speaks as though antifebrin might be of service.

The essay is an interesting review of the knowledge of epilepsy, past and present, especially from a physiological and pathological point of view, but it is a sad commentary on the state of knowledge in regard to it, that the profession should still be so powerless to combat it successfully.

TRANSACTIONS OF THE ASSOCIATION OF AMERICAN PHYSICIANS. Fifth Session, held at Washington, D. C., May 13, 14 and 15, 1890. Volume V. 8vo, pp. xxiv, 275. Philadelphia: Printed for the Association, 1890.

The present volume contains nineteen papers on medical subjects, all of them of a high degree of excellence. We desire to refer particularly to the paper of Dr. William T. Lusk on "Antisepsis in Midwifery," because it is a late utterance by a recognized authority on obstetrical procedures, and because of the importance of its teaching. After speaking of the great lessening in the mortality and morbidity from puerperal diseases which has followed the employment of antisepsis in labor cases, he details the method used in Bellevue Hospital. This consists essentially in preventing anything septic from getting in range of the woman. During child-bed no vaginal douches are given—they are given before it. The following sentence merits quotation: "The occasional appearance on the scene of an individual who uses his 'commonsense'—*i. e.*, one who does not believe there is any harm in witnessing an autopsy, or in visiting a companion in the erysipelas ward, or in holding the pus basin in an operation for pyothorax—is almost certainly followed by temperature elevations, which add fresh testimony to the efficacy of a rigid observance of antiseptic regulations." True midwifery antisepsis, Dr. Lusk says, "consists not so much in douching as in furthering physiological processes. Under normal circumstances a proper handling of the patient in the third stage of labor will effect more in the way of prophylaxis than Niagara. When, however, hands or instruments are introduced into the uterine cavity, the case is different. It would be hardihood then not to precede the operative measure by thorough vaginal disinfection." Dr. Lusk believes in the employment of the douche in fevers resulting from the absorption of toxine due to the putrefaction of clots, membranes and bits of placenta within the uterus; but he says it is to be remembered that this is a clumsy attempt to remedy the results of past remissness and that his own opinion is that the intra-uterine douche in child-bed is not indicated except when there has been slovenly help rendered by the attendant at the time of childbirth.

When the douche is to be used, Dr. Lusk employs first a vaginal douche, and, for intra-uterine injection, bichloride solution of a strength of 1 to 3,000, injecting not more than a quart. After the douche, he strongly recommends the introduction of an iodoform pencil containing two and one-half drachms of iodoform.

These quotations indicate sufficiently, without further comment, the thoroughly defensible position occupied by Dr. Lusk on the question of antiseptic midwifery. In most cases it is necessary because there has been neglect in keeping the woman and her surroundings in an aseptic condition.

A DICTIONARY OF PRACTICAL MEDICINE BY VARIOUS WRITERS. Edited by James Kingston Fowler, M. A., M. D., Fellow of the Royal College of Physicians, etc. 8vo, pp. xxvi, 942. Philadelphia: P. Blakiston, Son & Co., 1890. Price, Cloth, $5.00. Half Morocco, $6.00.

This is a dictionary and a concise treatise on the practice of medicine in one. Authors of well-known reputation have contributed the descriptions and written the articles upon subjects with which they are familiar. The result has been the production of a book of a high order of excellence. It is impossible in our space to review such a book and do full justice to it. One feature of it, however, is deserving of special mention: when diseases are treated of, the symptoms, diagnosis, pathology and treatment are all given. This makes the dictionary very much more valuable for students, while it is easy for those who do not desire to study any particular part to skip it. We can cordially commend the book to our readers as trustworthy and well up to the times.

PASTEUR AND RABIES. By Thomas M. Dolan, M. D., F. R. C. S., Edin., author of *The Nature and Treatment of Hydrophobia*, etc. Small 8vo, pp. ix, 83. London: George Bell & Sons, 1890.

Some one has said that nothing lies like facts, unless it be figures. In looking over this little brochure the conclusion is inevitable that some one is guilty of wilful deception, or else belongs to the class of persons once wittily described by Sir James Paget, as those "who would not for their lives tell a lie, yet who all their lives have been utterly unable to tell the exact truth." Dr. Dolan is an opponent of Pasteur and of anti-rabic inoculations. In his preface he quotes a letter received from Prof. Peter, of Paris, who declares that the mortality from hydrophobia in France has increased since Pasteur began his work, and that the latter is in the position of a physician who, when consulted by a patient with small-pox, should insert a second dose of the variolous poison in order to subdue the force of the first. The report of Dujardin-Beaumetz in his capacity of Health Officer in the Department of the Seine, shows that from 1882 to 1885, the four years before Pasteur's method was employed, the number of deaths in Paris was 38, while in the following four years, under his method, it was 37. Dujardin-Beaumetz ends his report by saying: "As Pasteur's treatment does not prevent the persistence of hydrophobia, we must still depend upon . . . the killing of

every dog which has been bitten by a rabid animal." Dr. Dolan tabulates 90 cases of death after treatment by Pasteur, in France, from November 1, 1885, to November 30, 1889.

It is evident from his book and from the opinions of others whom he quotes, that the day is passed when statistical statements emanating from Pasteur and his Institute will be accepted without close scrutiny, to see in how much they bear the construction put upon them and in how much they are consciously or unconsciously misconstrued.

New Remedies and Appliances

[In this department, notice will be given of Remedies, Food Articles, and Instruments or Surgical Appliances of which specimens are sent to the Editor; it will bear the same relation to these articles that the department of Book Reviews now does to books.]

Pavara Pills.

A specimen vial of Pavara pills, sent here by C. L. Topliff, of New York, contains a lot of oblong, gelatin-coated pills which are, as the label states, tasteless—that is, if soon swallowed; although the solubility of the coating is shown by the promptness with which the moderate bitterness of the ingredients is perceived if one of the pills is held in the mouth for a few seconds.

These pills have in our observation—which antedates considerably the receipt of the specimens—fully justified the claim of the manufacturer that they are both efficient and pleasant in the treatment of constipation, and we feel that it is safe to expect others who prescribe them to be well satisfied with their effects.

Correspondence.

What shall we do with our Pelvic Inflammatory Cases?

To the Editor.

Sir: Dr. Anna M. Fullerton has recently contributed a second paper to this subject in the *Annals of Gynecology*, for November, 1890, the first paper having appeared in the Medical and Surgical Reporter, August 16, 1890. In both papers Dr. Fullerton quotes liberally from my writings and statements respecting the value of electricity in chronic pelvic inflammations; and, though I am preparing for publication a careful review of this subject, with abundant proof, it is necessary for me to point out at once the inherent weakness of the conclusions of her second paper, which were reproduced in your last number.

As an apparent basis for her conclusions, the paper in the *Annals* contained a list of 27 cases of operations for pelvic disease. In this list only five cases had had electrical treatment—presumably of the kind available at the hospital of the Woman's Medical College. Of these five, three were cases of ovarian cysts, in which the use of electricity is universally condemned as useless. Of the other two cases one (No. 1 in the list) appears to have been treated two months with electricity and rest. At the operation "sclerosed" ovaries and inflamed tubes seem to have been removed. This patient did not die from the operation, but there is a singular and most eloquent silence as to its result on the pain of which the patient complained. The other case (No. 17) was one of hemorrhagic fibroma, in which a few treatments were said to have been followed by pelvic peritonitis—which may have been due to the bad technique prevailing in the clinic, as no mention of pus is made.

With one exception, therefore, this list of twenty-seven cases has no bearing whatever on the value of electricity in the diseases for which it has been recommended.

Before dismissing this list it may be of service to look at it more closely. In the series were twenty-three cases of amputation of the uterine appendages. Results: two deaths; twenty-one sexless women; and but two cases in which relief of symptoms after operation is noted. Both of these cases (Nos. 5 and 7), moreover, had other conditions than inflammation present, one being a simple and the other a dermoid cyst of the ovary.

Aside from the charge of ignorance on the part of electro-gynecologists, which Dr. Fullerton prints in cold type, the remainder of both papers is merely the advancement of a plea that abdominal section should always and invariably replace electricity and other conservative measures in the treatment of pelvic diseases, because without section no one can make a diagnosis. If this view were not so frequently expressed just now, it would be regarded as most remarkable. The same procedures among the doctors of the body politic would render courts and juries unnecessary and the one "panacea" of the suspected as well as the real diseases of society would be the hangman.

If electricity is stigmatized as a pretended panacea, what shall universal and purposeless abdominal section be called? Dr. Fullerton's vivisectional experiments lead her to think that any doubtful case may present either a

salpingitis, ovaritis, salpingo-ovaritis, hydrosalpinx, hemato-salpinx, abscess of tube or ovary, small dermoids, extra-uterine pregnancy, etc. I should like to ask if there is not one pathological process and one only underlying all of these conditions, except the last two? Wherever it is situated, the patient is suffering from an inflammation, and the aim of the scientific physician is to subdue it, whether situated on this side or that side of a certain tissue or membrane. Owing to the chemical and vital changes produced in living flesh by the galvanic current, it is a most efficient agent in the promotion of healthy action in sub-acute inflammations, especially when the physical laws governing its transmission permit us to pass a sufficiently dense current through the diseased part. Its very efficiency in arousing dormant tissue vitality contra-indicates its use in the advanced stages with purulent formation—at least unless a free exit to the pus is also arranged for. There is no question of the value of differential diagnosis between simple inflammatory conditions on the one hand and purulent collections and cysts on the other; but to perform a bloody and dangerous operation for the sake of knowing if an inflammation is on the inside or outside of the Fallopian tube is like splitting hairs with an axe. Electricity itself is a valuable means of differentiating these two groups; for, if the symptoms of a case are aggravated by it, the existence of an abscess may be diagnosticated with reasonable certainty. Unless gross carelessness is betrayed, this intensification of the symptoms is but evanescent.

It is idle to speak of "electricity" as dangerous. Any tyro who is capable of bridling this potent agency may practice vaginal applications, though no one but an expert should pass an electrode or anything else within the cavity of the uterus. Electropunctures and intra-uterine applications demand, like surgery, the possession of skill and experience on the part of operators. As to the prevalence of accidents from the use of electricity, it is notable that no proof of the statement is given by Dr. Fullerton, though it is easy to believe that such results may exist in a hospital in which this work is relegated to unskilled assistants, who are hampered by inadequate facilities and frustrated by a constant drain of the best material to supply the tables of ambitious operators. Electrical work that demands uterine sounding partakes, of course, of the well-known risk of that procedure, though it is my conviction that a mild galvanic current renders a sound less noxious than when the latter is used alone. Fortunately, the use of electricity is not restricted to this method, notwithstanding its usually preponderating efficiency. Danion and Championnière have even advocated a vaginal method in the treatment of fibroids.

It is to be regretted that Dr. Fullerton, in alluding to Dr. Bradford's paper on certain cases treated by me, which appeared in the *Annals of Gynecology*, March, 1890, confined herself to his somewhat ambiguous concluding words. If she turns to the body of the paper, she will find that the notes prepared by Dr. Bradford, with the critical assistance of Dr. J. M. Baldy, showed the following conditions in the cases after a year's interval:

Cured permanently, 5.
Improved permanently, 3.
Improved temporarily, 3.

Such was the verdict agreed upon as to the condition of these desperate cases at the expiration of a year from their original report, the jury consisting of two surgeons and one electrician. Facts thus arrived at are worth mountains of opinions, and I would suggest to Dr. Fullerton the adoption of a similar method of studying the *ultimate* results of the cases she reports.

Dr. Fullerton presents in both papers some observations on the relative value of old maids and ovaries. As to the latter, I beg leave to submit that an unmarried woman is not a competent judge. Until women engaged in rearing families, and more especially their husbands, decide that these organs are useless I shall continue to urge that all means be exhausted before their removal is decided upon; and I think that both common sense and public policy will sustain me.

Yours truly,
G. Betton Massey, M. D.
Philadelphia.

Anencephalous Monster.

To the Editor.

Sir: On October 22, 1890, we were called to attend Mrs. S., who was reported as being in labor for the past twenty-four hours. On examination we found the patient very nervous, with cold feet and hands and very feeble action of the heart. The first stage of labor was not over, and there was a face presentation. On inquiry, we found Mrs. S. to

be 39 years old, a multipara, of nervous temperament, very much emaciated, having suffered pain for three months previous, for which she claimed to have taken four grains of morphia daily. She had taken no morphia for the past two days, thinking it would interfere with the progress of her labor. We gave her some morphia hypodermically and then the labor progressed very rapidly, and terminated in three or four hours under the combined use of morphia and chloroform.

The fetus was a boy, weighing six pounds and fully developed, with the exception of the head, which is sunken between shoulders and has neither forehead nor vertex, the vault of the skull and the brain being entirely absent. The base of the skull was surmounted by a blood tumor. The face was livid and over-developed, and was directed obliquely. The nose was large and flattened, the eyes projecting and the mouth open. The child lived twenty-two hours, during which time it had tonic and clonic convulsions.

The mother attributed the abnormality of her child to seeing a drowning hog, which was taken from the water and its brains knocked out in her presence.

Yours truly,

DRS. LUCAS & PANKAKE.

Alma, Arkansas.

NOTES AND COMMENTS.

Treatment of Enlarged Prostate.

In the *American Journal of the Medical Sciences*, November, 1890, Dr. W. T. Belfield has a paper on "Operations on Enlarged Prostate" in which he says:

An estimate of the value of radical operations must be based upon a comparison with the results of simple drainage of the bladder; since the latter is included in the former and alone secures cessation of existing cystitis, subsidence of the congestive œdema of the prostate, and an improvement —more or less temporary—in the evacuation of the bladder. The radical operation should accomplish more; it should restore voluntary and complete urination in the individual who has long been largely or entirely dependent upon the catheter. For this estimate many of the 133 reported cases are useless; for in some the previous and subsequent history is not recorded; in others the operation was made for acute retention without previous dependence upon the catheter (where simple drainage would have afforded relief); and in a third class the prostatic enlargement was complicated with a calculus, to whose removal the recovery of the vesical function might be largely ascribed. Excluding these, there remain 41 cases wherein the catheter was indispensable for periods varying from several months to seven years prior to operation. In 32 of these 41 voluntary urination was restored and maintained during the period of observation, varying from a few months to two years; in only few is it, however, definitely stated that the evacuation of the bladder was complete as well as voluntary; in several, residual urine was noted and the daily passage of the catheter was advised as a precautionary measure. In 9 of the 41 cases voluntary micturition was not restored. As elsewhere observed, it seems probable that the failure in some of these was due to incompleteness of operation.

The abstract utility of prostatectomy is as yet clinically restricted by the fact that so many patients requiring the operation are, when they reach the surgeon, too feeble to endure it. For this reason Dr. Belfield has refused to advise the operation in several cases; he made simple drainage by perineal urethrotomy in five (with one death); and in four others (two fatal), in which the suprapubic incision was imperative for the extraction of a calculus, he declined to interfere with prostatic tumors whose removal presented no mechanical difficulties—simply because the enfeebled condition of the respective patients forbade all operative measures that were not absolutely necessary for immediate relief. In time patients will be educated to the knowledge that danger lies not in the operation but in the delay whereby the urinary organs are disorganized.

The various operations mentioned represent as many stages in the development of surgical conceptions as to the nature and accessibility of the prostatic obstacle. The operations of Mercier and Bottini may, doubtless, by a happy chance, secure occasionally complete success, though inapplicable to most cases; perineal incision and excision of prostatic obstructions have a wider range of usefulness, seriously restricted, however, by the mechanical difficulties in the detection and removal of the common intra-vesical growths; supra-pubic cystotomy affords satisfactory access to these frequent tumors, but sometimes fails to clear

the obstructed urethra; the combined supra-pubic and perineal approach seems alone to fulfil every indication in every case. There is, therefore, from the anatomical standpoint, no choice of operation; supra-pubic cystotomy, with or without a supplementary *boutonnière*, as the peculiarities of the prostate in a given case may require, is in the abstract *the* operation. Yet the interests of the patient will, doubtless, sometimes be better served by a compromise with the requirements of his prostate; perineal prostatotomy is perfectly free from anatomical dangers, and, because so quickly completed, involves less peril from the anæsthetic. It is, therefore, safer (mortality 9 per cent. against 16 per cent. by supra-pubic prostatectomy); it affords temporary relief in all cases and a radical cure in a fair minority—for which reasons it should, in the writer's opinion, be the operation of choice in feeble patients.

As to the technique of supra-pubic cystotomy, the Petersen rectal bag has been quite largely abandoned and the modified Trendelenburg position adopted for eliminating the peritoneal fold from the field of operation. The transverse incision of the soft parts and Helferich's partial resection of the symphysis seem to be regarded as unnecessary features. The extreme distention of the bladder, formerly considered an essential safeguard, is no longer practiced, since with the patient in the inclined posture an almost empty bladder can be opened with safety.

An important advance in the removal of prostatic obstruction is the enucleation of all accessible masses in the substance of the organ instead of a simple levelling off of projecting tumors with scissors or cautery; by this means not only the salient middle lobes, but also the no less obstructing, though less obtrusive lateral enlargements, are easily removable. This process of enucleation obviates the necessity for the operation suggested by Dittel, under the title of "lateral prostatectomy."[1] After emphasizing the importance of the neglected lateral lobes in the induction of retention, and criticising Harrison's plan of treating them by prolonged pressure as inefficient, Dittel shows that they can be reached by separation of the rectum from the prostate; and by operation upon a cadaver with lateral enlargement of the prostate, he proved that the excision of portions of the lateral lobes from the rear—without opening the bladder—relieved the prostatic obstruction by permitting the vesical surfaces of these lobes to fall apart. He admits that supra-pubic cystotomy would also often be necessary for the removal of intra-vesical obstacles; and that the two operations, even if separated by an interval of weeks, would rarely be sustained by the same subject until patients are educated to submitting to them at an early stage of prostatic disease.

Dittel makes no allusion to the fact that the lateral lobes can be and have repeatedly been removed by enucleation after supra-pubic cystotomy. Of the several surgeons who have independently adopted this measure McGill deserves especial mention;. in several instances he has enucleated lateral masses weighing from one-half to two ounces. The ingenious operation suggested by Dittel seems, therefore, to have been anticipated by a much simpler, safer and more practicable means of attaining the same end.

Prolonged retention of a tube in the perineal wound, as advised by Harrison, has been attended in his and other hands with one unpleasant result—the persistence of a permanent and obstinate fistula.

Wishard, of Indianapolis, has successfully practiced a means for obviating this objectionable sequel: When the tube is finally removed he curettes the granulating surfaces, incises the anterior and posterior angles, and closes the entire wound by sutures, drawing the urine by catheter for several days. By this means he secured immediate and complete union after drainage for periods up to eighty-one days.

[1] *Wiener med. Woch.*, No. 19, 1890.

Castration for Mollities Ossium.

The *British Medical Journal*, Nov. 1, 1890, says editorially:

Of all the more serious impediments to labor, none can be graver than the pelvic deformity produced by mollities. The disease itself is most distressing over and above its ill effects on the genital canal. No doubt as far as fatality is concerned, it is as bad to die after labor delayed through rickety deformity as to perish in the same manner when mollities is the source of pelvic malformation. A rickety pelvis, however, causes little trouble except during labor. It is not incompatible with health, strength and beauty. Mollities, on the other hand,

always involves impaired health, it also cripples and disfigures the unhappy patient. Rickets cannot be made worse by pregnancy. Mollities, on the other hand, is not only aggravated by gestation, but tends to advance at each menstrual period. This fact, associated with the now frequent practice of removal of the appendages for chronic inflammatory disease, has set authorities thinking about the justifiability of that practice for the cure or check of mollities. To remove the ovaries lest a woman should bear more children is in any case questionable and under many circumstances almost criminal. To remove them in order to check a grave disease seems, on the other hand, quite justifiable. The practice entails sterility, but not as a direct aim; barrenness is simply an inevitable result as after double ovariotomy.

Drs. Fehling and Truzzi have carried these principles into practice and each of these obstetricians communicated the results of their practice to the Section of Obstetrics at the Berlin meeting of the International Medical Congress last August. Fehling, of Basel, has removed the ovaries nine times with the object of remedying mollities. The first operation was performed nearly four years ago. Eight of the cases recovered, and the progress of the disease was checked. One died from obstruction, through adhesion of the intestine to the uterus which had been fixed to the parietes—a warning, by the way, to those who practice hysterorrhaphy. Truzzi, of Milan, has operated twice, both patients recovering. The second case was non-puerperal; it is noteworthy that though the ovaries appeared healthy, a small sarcomatous area was found in the left, which was slightly enlarged. Fehling noticed unusual vascularity of the appendages in his cases, the arteries being enlarged as well as the veins. He found no characteristic miscroscopic changes in the ovaries. He noted a marked aggravation of the symptoms at each menstrual period, as a distinct feature in the previous histories of his patients. The steady diminution and ultimate cessation of the characteristic pains in the bones was one of the most satisfactory results of operation. Women with mollities are, as a rule, prolific; Dr. Fehling considers that this fact indicates abnormal activity of the ovarian functions. Still, the disease has been known to progress for many years in women who bore no children during that space of time; some cases of the kind were operated upon by Dr. Fehling, with the result that the mollities ceased to progress. That authority believes that the ovaries exert a reflex action on the vaso-dilators of the vessels of the bones, causing passive hyperemia followed by active absorption of the bone salts. Removal of the ovaries removes the exciting cause, so that the disease makes no further advance. It cannot be denied that Drs. Truzzi and Fehling have justified their bold proceeding, and the practice of excision of the ovaries for mollities ossium bids fair to become an established operation. Fortunately, opportunities for performing it will be rare in this country, the disease being very infrequent in the British Isles.

Operation for Cleft Palate.

Mr. Davies-Colley, Surgeon to Guy's Hospital, has published in the *British Medical Journal*, October 25, 1890, an interesting and well illustrated paper, in which he describes an operation for cleft in the hard palate, for which he makes the following claims.

1. There is less hemorrhage, for on the one side of the palate very few vessels are wounded, while on the other side the incision does not extend as far back as the foramen for the large descending palatine artery; and in dissecting back the triangular flap, it should be remembered that all the vessels which are divided are exposed to view, so that their orifices can be readily compressed by the sponge.

2. The parts can be cleanly dissected back, without so much bruising as is necessary in the ordinary operation.

3. Nothing is cut away.

4. There is very little tension after the operation. The flap lies loosely in its position, so loosely that I have often had misgivings that it would not unite; and as there is no pull upon the sutures they do not ulcerate through, and may be left for five or six weeks after the operation. This gives an opportunity for the flap to unite by granulations if union by the first intention has failed.

5. He has never observed any tendency to sloughing in the flap.

6. The upward pressure of the tongue, which so often causes separation of the flaps when the ordinary operation has been performed, especially in young children, is here beneficial. When the mouth is closed it acts as a splint to keep the flap in its proper

position, and press it firmly against the raw surface upon the other side.

7. The bridge is a very strong one, consisting as it does of two layers of muco-periosteum united by their raw surfaces.

8. This operation can be performed with success at a much earlier period than the ordinary operation. It is easy by these means to firmly unite clefts of the hard palate in infants between the age of one and two years. This is a great advantage, not only with respect to the mastication of food and the learning to talk, but also in diminishing the deformity of the face, the broadening of the bridge of the nose and the separation of the cheek bones, which are so often noticed in these patients.

Mr. Davies-Colley says the disadvantages of this method are: (1) the hard palate alone is united; (2) a foramen is generally left at the front part of the cleft. This, however, either tends to disappear, or can be closed in later life.

He has endeavored to unite the sides of the soft palate at the same time, but without success. On the other hand, it should be remembered that by securing a firm union of this kind in early life between the palatal processes of the superior maxillæ and palate bone the sides of the cleft in the soft palate are approximated, and that they may be easily united a few months later. In the young children upon whom he has operated he has found considerable difficulty in subsequently uniting the front part of the cleft of the soft palate, while the posterior two-thirds or three-fourths are readily brought together. In two patients over the age of 12 he found no difficulty in closing the gap thus left.

In conclusion, Mr. Davies-Colley strongly recommends this operation for the consideration of surgeons: 1. In the cleft palate of infants. 2. In patients on whom the ordinary operation for cleft of the hard palate has failed. 3. Where the separation of the sides of the hard palate is too great to be bridged over by the ordinary operation.

Caustic Lime for Purification of Sewage Water.

The *Engineer and Building Record*, November 15, 1890, says:

Dr. H. Weigmann, of Kiel, Germany, contributes to the *Gesundheits-Ingenieur* an interesting article on the above subject. In the pamphlet of foreign abstracts of the British Institution of Civil Engineers, the following resumé of it is given. While admitting that the purification of sewage water by means of irrigation is the more perfect system of treatment, Dr. Weigmann points out that in certain cases some chemical process has, for various reasons to be employed. Notwithstanding the numerous substances which have been proposed, lime still holds the foremost place. The caustic lime combining with the carbonic-acid gas, a product of decomposition always present in sewage water, yields a bulky precipitate of calcic carbonate, which mechanically entangles the suspended impurities and effects a rapid clarification.

Recent experiments respecting the action of lime have shown this substance to possess such excellent disinfecting properties that it seems that the lime treatment is among the best of the precipitation processes. As one result of the use of lime, it is pointed out that the substances in solution are thereby invariably increased rather than diminished in quantity, though the recent researches of Schreib tend to controvert this theory. In order to arrive at accurate conclusions, careful estimations of the amount of chlorine in the sample, both before and after treatment, are advisable. Dr. Weigmann's experiments have led to the conclusion that from the clarified effluent after the lime treatment there is a considerable evolution of ammonia and other nitrogeneous gases, and he states that though water which has been rendered so strongly alkaline as to destroy all the bacteria therein cannot decompose so rapidly as water teeming with bacteria (which are the active exciters of putrefactive changes), there can be no doubt that, owing to the dissolved lime, an important change takes place in the condition of the organic substances in solution. Dr. Weigmann insists upon the necessity for a rapid separation of the sludge from the water in order to put an end to the changes which take place in the organic matters entangled with the calcic carbonate, and points to the advantages, on chemical grounds, of passing the sludge through a filter-press, as soon as possible after deposition, as is done, for instance, in the works at Halle.

In addition to its powerful action in destroying the bacteria and germs of every kind, there can be no doubt that lime is a strong disinfectant. The tendency of alkaline sewage water, after it has, by means of carbonic-acid gas in the atmosphere or in the river

water, parted with its dissolved lime, is to become again rapidly charged with bacteria; but these are by the self-purification powers of running water speedily rendered innocuous or converted into the food-stuff of water-plants, and it is pointed out that the previous lime precipitation has removed all the germs of a pathogenic character, and the new growth of bacteria are probably of a non-dangerous character.

Ligation of Uterine Appendages for Hemorrhage from Myoma.

Dr. Michael Beverley reports in the *British Medical Journal*, November 1, 1890, the case of a woman 34 years old admitted to the Norfolk and Norwich Hospital, April 5, 1890, for profuse menorrhagia.

On examination a swelling could be felt externally, about the size of a cricket ball, in the left hypogastric region; it was movable and painful. External examination produced rather profuse loss. A tumor could be felt by vaginal and rectal examination; it moved with the uterus, which admitted the sound to 2½ inches. Diagnosis of uterine fibroma was made. The patient, who was anemic and weak, complained of bearing down, and some difficulty in defecation. She had been twice married and had had one child and several miscarriages. Her second husband died twelve months before her admission, so that she had to earn her own living. This had been lately impossible owing to constant uterine hemorrhage.

At a consultation of the staff Dr. Beverley proposed removal of the appendages; this was assented to, and was attempted April 30. The ovaries were, however, found to be so firmly bound down by adhesions within the pelvis that their removal appeared to be almost impracticable; consequently the operator raised the uterus partly out of the abdominal incision, and applied two ligatures round the Fallopian tube and broad ligaments on each side, close to the uterus, and divided the tubes between the ligatures. The operation was performed under the carbolic spray.

The patient made a rapid and uninterrupted recovery. Her only complaint fter the operation was pelvic pain, which required the use of hypodermic injections of morphine to allay it. The temperature chart was very even, 99.50° F., being the maximum. There was no uterine hemorrhage nor discharge after the operation; and she left the hospital quite well, on M. 24, twenty-four days after the operation. Her medical adviser, Mr. Shann, of Lowestoft, informed Dr. Beverley, in July, that up to that date she had had no recurrence of her symptoms and remained well.

This case is recorded for the purpose of eliciting an expression of opinion, for future guidance, under similar circumstances. Removal of the appendages for the arrest of uterine hemorrhage in fibromyomata of that organ is now become a recognized mode of treatment (in otherwise suitable cases). In most provincial hospitals, every now and then, must occur cases similar to this now recorded, in which the removal of the ovaries appears to be almost impracticable to the ordinary hospital surgeon. What in these cases do the specialists recommend? Are the ovaries to be pursued to their hiding places and shelled out of their nests? or is it sufficient to ligature the tubes as I elected to do in my case? And, if so, what will become of the cut off ovaries; and what chances has the patient of ultimate cure?

Double Uterus and Vagina.

In the *Bolnitchnaia Gazeta Botkina*, No. 42, 1890, p. 986, Dr. Vladimïr A. Vasten, of St. Petersburg, publishes an account of a rare and interesting case of double uterus and divided vagina, in which a surgical interference became necessary.

A merchant applied to the writer with complaints of his wife being sterile and incapable of sexual intercourse. The patient, a somewhat anemic and thin, but regularly-made woman, twenty-five years old, had begun to menstruate after her sixteenth year. The catamenia recurred regularly every four weeks, and lasting three or four days, but were always accompanied by abdominal pain and of late by hysterical fits. She had married at eighteen, any attempt at coition proving invariably unsuccessful and exceedingly painful. On examination, the external genitals were found to be developed quite unusually; but the vagina was double, being divided by a septum one-half inch thick from the vaginal inlet up to the fornix. A portion of the partition below was detached from the posterior vaginal wall at the distance of three centimeters. It had been torn off during initial attempts at sexual intercourse, the woman having had profuse hemorrhage for the first three months of her marital life. The vaginæ had a normal

ength, but were rather narrow, the introduction of a Ferguson speculum two and one-fourth centimeters in diameter causing pain. In each vagina there was present a small-sized uterine cervix with a very narrow circular external os, discharging an abundant viscid and turbid mucus, the uterine bodies deviating laterally at the level of the inner os, the left womb measuring eight and the right eight and one-half centimeters in length. As repeated examination showed, the wombs were menstruating simultaneously and equally abundantly. Both the husband and wife expressing an ardent wish to get rid of dyspareunia and to improve the chances of conception, Dr. Vasten excised the whole septum, except a small crescent-shaped flap between the cervices, and closed the wounds with interrupted silk sutures. Hemorrhage was but trifling. For a day the patient had obstinate vomiting, but otherwise the after-course was most satisfactory. On the ninth day the woman got up; on the tenth the sutures were removed, the wounds healing by first intention, except a small area, which suppurated. On the fourteenth the woman was discharged quite well. When seen some while afterwards, she was in high spirits; coition and the catamenia had become normal and the hysterical fits had ceased to occur.

Dr. Vasten adds that this is a third case of double womb and vagina, seen by him during the last twenty years. None of the patients were aware of the defect, notwithstanding their having been previously examined by various gynecologists. On the whole, Dr. Vasten believes that the anomaly in question occurs far more commonly than is usually supposed.

Tea a Cause of Cold Feet.

Mr. Hutchinson says in the *Archives of Surgery*, July, 1890, that he once advised a lady to drink more tea. "I cannot touch it," was her reply. "It makes my feet icy-cold, and wet with cold perspiration." On further inquiry, she assured Mr. Hutchinson that she was quite certain of her facts, and had often tested them. She thought that the perspiration was usually of the soles chiefly. Her hands were, she thought, also made cold, but not so definitely as her feet. Mr. Hutchinson says he had long been familiar with the fact that tea made the feet cold, but did not know that cold perspiration attended it. It does not do so in all persons. The coldness is caused, he believes, by contraction of the arteries, for the feet at the same time shrink. Alcohol has usually a precisely opposite effect.

Elder Bark as a Diuretic.

The *Chemist and Druggist*, November 8, 1890, says that flowers, fruit and bark of the elder-tree (*Sambucus nigra*) have had a reputation from a very early time for their diuretic properties, but for many years they have been little used. Recently, however, several Continental physicians have been experimenting with the fresh inner bark in chronic Bright's disease, acute nephritis, and other complaints, using a sweetened decoction of the drug. In most cases there was distinct improvement, and the diuresis produced was copious.

RESOLUTIONS.

IN MEMORY OF RICHARD J. LEVIS, M. D.

At a meeting of the Faculty of the Philadelphia Polyclinic and College for Graduates of Medicine, the following preamble and resolutions were unanimously adopted.

WHEREAS, The Divine Ruler of the universe has seen fit to remove from among us Dr. Richard J. Levis, our friend and colleague; therefore be it

Resolved: That not only in the Emeritus Professor of Surgery of the Philadelphia Polyclinic, but the whole medical profession has lost an honored and faithful co-laborer; and the community has cause to mourn a skilful and learned physician and honest and sympathizing friend.

Resolved: That by his kindness of manner, by the thoughtful interest which he always manifested in the younger members of the profession, by his encouragement, his earnestness and his example, he had endeared himself to all, and that we fitly honor and cherish his memory. We must emulate his zeal and vie with each other in carrying forward the great work in which he was so ardently engaged.

Resolved: That we tender to his family, in this sad hour of affliction, our heart-felt sympathy.

Resolved: That these resolutions be handed to the family of our beloved colleague and to the medical journals.

(Signed) THOS. J. MAYS, *President*,
S. SOLIS-COHEN, *Secretary*.

FOR THE CURE OF

NERVOUS HEADACHES

SEDATIVE EFFERVESCENT

BROMO (WARNER & CO.) SODA

℞ Caffein 1 grain, Brom. Soda 30 grains in each heaping teaspoonful.

Useful in Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Seasickness and Epilepsy.

Dose and Composition.—A heaping teaspoonful, containing Bromo-Soda 30 grs., and Caffein 1 gr., in half a glass of water, to be repeated once after an interval of thirty minutes if necessary.

EFFERVESCENT ANODYNE

BROMO (WARNER & CO.) POTASH

℞ Caffein 1 grain, Bromide Potash 20 grains in each heaping teaspoonful.

Useful in Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Seasickness and Epilepsy.

☞ **Physicians** desiring the Potash Salt can obtain the same by ordering or prescribing **Bromo-Potash (Warner & Co.)**, the composition of which is: Brom. Potash 20 grs., Caffein 1 gr.

☞ The composition of the above effervescent salts is such as physicians can use with confidence, and you will please specify **Bromo-Soda** or **Bromo-Potash, Warner & Co.,** when ordering or prescribing to avoid the substitution of other "Bromos." Prepared only by

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

CLOSURE OF VULVA FOR VESICO-VAGINAL FISTULA.—FIBROID TUMORS.

BY WILLIAM GOODELL, M. D.,

PROFESSOR OF GYNECOLOGY, UNIVERSITY OF PENNSYLVANIA.

Closure of Vulva.

Gentlemen: This woman had her first labor twenty-five years ago, and is now fifty years old. She lived then in the country, and was four miles from the nearest physician. She fell into labor—her first and only one—with a shoulder presentation. Much delay took place before the doctor reached her side, and then he found that the waters had escaped, and the shoulder was so jammed down that he could not perform version. He sent for help, and two brother physicians came to his aid; but they also found it impossible to turn the child and deliver the woman. By this time many hours had elapsed, and while they were debating the propriety of performing embryulcia, the child was turned and delivered by the rare mechanism of spontaneous evolution. Of course the child was dead; but that was not the only misfortune; for the bladder and the surrounding pelvic tissues and organs had been so seriously compressed as to cause sloughing of the womb, the whole base of the bladder, the entire track of the vagina, and all of the urethra. The vagina nearly closed up by cicatricial contraction and the urine was constantly dribbling from her person, making her very raw, bad smelling and miserable. She consulted eighteen physicians; but nothing could be done for her. Finally she came to me in 1877; and I performed the following operation with her consent, telling her that I did not know whether it would succeed or not. It consisted in making an opening between the vagina and the rectum—in other words, a recto-vaginal fistula. Then I closed up the whole vulvar opening, and thus converted the rectum into a bladder. At first the rectum so resented the presence of the urine, that she had to pass her urine every few minutes, and I was afraid that I would be compelled to reopen the vulva. But finally rectal tolerance took place, and she became able to hold her water in the rectum for six hours at a time.

For thirteen years she got on very well; but a few months ago, probably through something undigestible which she had swallowed—perhaps a bone—a small fistulous opening occurred near the arch of the pubic bone, from which the urine dribbles. So she has come to-day to have it closed up. She is an opium-eater, and she looked so pale that I had her urine examined. Much albumin was found; but whether it is secreted from her kidneys, or comes from the admixture of feces in her urine, I cannot say. But we shall take additional precautions while administering the ether; for ether is obnoxious to diseased kidney, especially when caused by compression from large tumors; and we may then have arrested secretion as a result. Under such a circumstance, namely, the presence of a large tumor, I usually give chloroform.

The operation to-day will consist in simply freshening the sides of the sinus, and then bringing the raw edges together. My assistant has just syringed out the fistulous track with a 1 : 2,000 sublimate solution, preparatory to the operation. But he forgot that the vagina communicates with the rectum, and that this antiseptic solution, while quite harmless in the vagina, is capable of doing much mischief in the rectum. So we wash out the rectum with large quantities of water, and thus get rid of the danger of having the poison absorbed.

This episode reminds me of another,

which filled me with great anxiety at the time, but at which I can now laugh heartily when I think of it. Early last summer I removed a malignant growth from the cervix uteri of a woman and ordered daily douches of a 1 : 2,000 solution of corrosive sublimate: that is to say, a tablet of seven and a half grains of corrosive sublimate was put into a quart of water which was injected by the nurse into the vagina. As the patient convalesced, she would sit on the commode and would herself insert the nozzle of the syringe into the vagina. But on one extremely hot evening she unconsciously introduced the nozzle into the rectum. The nurse, not knowing how very much astray the nozzle had gone, pumped away until very nearly the whole quart had been taken up. Suddenly the woman began to feel severe rectal pain, and then she realized what she had done. The nurse, although very greatly alarmed, was quite equal to the emergency. She sent in great haste for me, and at once injected quart after quart of water until the lower bowel was well washed out. I hurried the messenger to the nearest drug store for lime water, and then ran all the way to my patient's house, which was nearly half a mile distant. A quart of lime water was now thrown up into the bowel, as an additional precaution; but it was hardly necessary, as the previous repeated injections by the nurse had carried off the poison. Beyond a slight soreness of the rectum, which lasted for twenty-four hours, my patient suffered nothing. But what with the heat, the anxiety, and my hard run, my underclothing became so drenched with perspiration that I had to change them all when I reached home.

But, to return to our patient. It sometimes happens in these cases of violent injury to the soft parts from labor, that menstruation is permanently arrested. Exactly why this happens, I cannot say; but so it was with our patient when I operated on her in 1877; and I have repeatedly seen it in other cases. In one of these cases—that of an unmarried girl—I never could find the cervix uteri, so destroyed and matted together were all the pelvic organs from a neglected labor. Twice, in vain efforts to discover it by dissection, I got into the peritoneal cavity. As she had lost the whole base of her bladder, and also had a very large recto-vaginal fistula, caused by the general sloughing, I closed up her vulva, as in the patient before you. In her case also, the rectum needed education to tolerate the presence of urine. But ultimately it made a very good bladder. If my memory is not at fault, these are the only two cases in which I was forced to close up the vulva. I have, however, on one occasion closed up the womb, or rather the cervix, in the bladder, so that the woman menstruated afterwards into the bladder and out through the urethra.

While talking, I have been denuding the edges of the fistula. These are coaptated by shotted wire sutures. In order to avoid all tension on the parts by the accumulation of urine in the vagina, I shall insert a short catheter into the rectum. These sutures will not be removed for at least a week; but if there should be a leakage from the wound they will be kept in for two weeks, so as to aid the granulating surface to close up. The wire used was No. 31, which is the finest used in gynecological work. My rule in the selection of wire is, to use the finest compatible with safety—the finest for plastic operations on the cervix and on the bladder; the heaviest for perineal tears.

The lesson which we get from this case is to act promptly in obstetric emergencies. My rule is always to interfere, and that promptly, in certain conditions. For instance, in a face presentation, if the occiput cannot be brought down to become the presenting part, I always turn. In a breech case, I make it the rule to bring down one leg; and I thus have the labor wholly under my control. In a shoulder presentation I always give ether, and turn as soon as possible, by the bimanual, or bipolar, method. The most common cause of vesico-vaginal fistula is delay in a head-first labor, after the engagement of the head. Therefore this lesion is more likely to happen in cases of moderate disproportion than in extreme ones; for in the latter the head cannot engage, and it has to be opened before it can delivered.

Medicinal Treatment of Fibroid Tumors.

I expected to operate before you upon this case; but, upon thoroughly examining this woman and learning her history, I have decided not to do so; I have changed my mind and come to this let-alone treatment for some reasons which I wish to impress upon you. The patient is an unmarried woman, forty-two years old, and was beginning to go as long as seven weeks without seeing her menstrual periods, when, no

long ago she began to menstruate profusely every three weeks, or, at least, to have severe hemorrhages from the uterus at these intervals. A few weeks ago her physician discovered, and informed her that she had a tumor of the womb; and she, woman-like, wished to "have it taken out at once," and gave him no peace until he brought her to me. So by agreement I came over to see her yesterday and decided not to operate, or, at least, not to operate now, as I shall presently explain to you. She is forty-two years old; therefore, approaching the climacteric, and her monthly periods had begun to dodge, before these violent hemorrhages set in. Now what causes these floodings? Usually one of only two diseases: either a cancer of the cervix uteri, or a uterine fibroid. If she had been the mother of children, the probability would be that she had a cancer; because this disease usually comes from a cervical tear. But as our patient has never had a child, the tumor turned out to be a uterine fibroid, as under such circumstances it usually does. Old maids and sterile women are very liable to have fibroid tumors of the womb, and very unlikely to have a uterine cancer. Yes, I fully agree with the diagnosis of her physician. She has multiple fibroid tumors of the uterus. There are, at least, three of them that are sub-peritoneal and attached to the left side of the womb. By them the uterus has been pushed over to the right side, and the left ovary is probably much dislocated in relation to the surrounding parts. Now, if any operation were performed, it would have to be one of two, either of which would be difficult and dangerous. The more common of these two is oöphorectomy, with the hope of stopping menstruation and thereby relieving the certainly periodical, and more or less constant congestion of the womb. But this operation would probably be difficult, if not impossible, on account of the size of these multiple tumors. For, sometimes the ovary in these cases has no pedicle, as it is drawn down in close relation to the tumor. Sometimes it is stretched to a mere ribbon or a mere cord several inches in length. Sometimes, indeed, it is so imbedded in the tumor as not to be enucleated safely. The other operation would be the removal of the whole mass—womb, tumors and appendages. But there is some risk attending this operation—a risk to life which her condition does not warrant. Moreover she does not live by manual labor, and therefore she can take care of herself until the change of life takes place, which will bring about the cure of her disease. Nature cures, by causing atrophy and absorption of these growths, whose nutrition is interfered with by the cessation of menstruation.

To tide the woman over to that time, needs some treatment. As she has plenty of fat and blood, she is to have her bowels kept open by saline cathartics; such as Rochelle salts, Seidlitz powders and citrate of magnesia. Then she is to take after each meal twenty drops of the fluid extract of ergot and ten grains of ammonium chloride. The effect of the ergot will be to contract the muscular fibres of the uterus, and thus, by compressing the vessels, to lessen the blood supply of the tumor. Sometimes the womb contracts so firmly as to squeeze the tumor out of its uterine nest into the uterine cavity and expel it per vaginam. The ergot may cause headache, vertigo and nausea, through vasomotor disturbance; and then the dose must be reduced, but not discontinued wholly. The ammonium chloride acts as a resorbent, and clinches the action of the ergot. For continuous treatment, it should not be given in tablet form; as it is likely then to settle itself in one portion of the stomach and dissolve there, irritating the mucous coat of that portion. Give it largely diluted in water, and then it will mix with the contents of the stomach and get still further attenuated. This treatment by ergot and ammonium chloride should be continued for months. I have seen great results follow the continued use of these medicines. The hypodermic administration of ergotine is still more efficacious; but it gives so much pain, so discolors the skin and is so liable to be followed by abscesses or very painful indurations, that I now rarely resort to it.

Homœopathy in Russia. — Homœopathy is said to be spreading in Russia, especially in the upper social strata. Societies for the propagation of the Hahnemannian doctrines have recently been established at Tschernigow, Odessa and Warsaw. As has been noticed in other countries, the clergy are conspicuous among the supporters of the great medical heresy, and in Russia the military mind seems also to have an elective affinity for globules and infinitesimal dilutions. At Tschernigow, one of the founders of the new Society is a Bishop.

HYDATID CYST OF THE LIVER.—PLEURISY ASSOCIATED WITH TUBERCULOSIS.[1]

BY JOHN H. MUSSER, M. D.,

ASSISTANT PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA, PHYSICIAN TO THE PHILADELPHIA HOSPITAL, ETC.

Obstructive Jaundice Due to a Hydatid Cyst.

Gentlemen: A little sooner than I anticipated I am able to demonstrate the morbid anatomy of the case of obstructive jaundice I brought before you last week. You no doubt remember the patient, whose previous history we did not know, except that his jaundice was of a moderately chronic duration, lasting for two months. The fact that he was jaundiced because of obstruction to the bile ducts was plain enough, the question was as to the cause. Without any definite data to sustain us, we came to the conclusion that his condition was due either to carcinoma of the biliary passages, or to their obstruction by gall-stones. In speaking of some of the causes of obstructive jaundice, you will remember that I referred also to hydatid cysts, and round worms as very rare causes of such a condition, so rare that one would hardly be justified in making such a diagnosis except by the most positive exclusion of the other causes of jaundice. You will also remember that I suggested that the question could be solved by means of the exploratory needle and by laparotomy, but that the patient was so ill that these means were scarcely justifiable. Moreover, his blood was so seriously poisoned by the retention of bile, that on this account an operation would not be justifiable, since the patient would probably die of hemorrhage, either from a copious escape of blood at once or from constant oozing. The fatal termination resulted four or five days afterwards, his stupor deepening into coma and death.

The autopsy showed a very remarkable state of affairs. There was no disease outside of the ducts or liver. The tissues and structures showed simply an impregnation by bile. The large common duct was very much enlarged, exceeding the size of my thumb. It could be readily distinguished from the vein alongside of it, and was easily isolated. There was not a sufficient amount of adhesions to cause any doubt as to the relation of the parts. The gall-bladder was enlarged, and distended with a mucoid fluid. That portion of the duct extending from the cystic duct to the duodenum was patulous. The biliary ducts in the liver were dilated, and just above the entrance of the hepatic duct into the liver there was a large dilatation, apparently of the duct, but which I believe to be a cyst which had ruptured into the duct and in that way occluded the canal with the hydatid membranes. The duct itself was not the seat of any disease. This cyst, hydatid in nature, was large enough to hold a good-sized lemon. There was a second cyst whose contents still remained in the periphery of the left lobe of the liver. It had nothing to do with the cause of the jaundice. The contents of the larger cyst, by causing an obstruction of the duct, had given rise to the jaundiced condition of the patient. These large shreds of membrane, which I here show you, could never have passed through the duct into the duodenum. Nature made an effort to accomplish this, but was not able to sufficiently distend the duct.

The question now is, could this man have been relieved by an operation? I think he could, because of the size of the duct. There were so few adhesions that access to the ducts could have readily been had and a cholecystotomy performed relieving the obstruction, while a rubber tube would have drained the cyst, and the patient would probably have recovered. Of course there would have remained the other cyst, which would gradually have increased in size; and, knowing this history of the patient, a second operation could have been performed, either by laparotomy or aspiration. The patient just missed his chance of recovery by not entering the hospital a few weeks earlier.

The lesson we learn from this case is, that an exploratory operation in obscure cases of obstructive jaundice is always advisable. Opening the gall-bladder simply, would not have been of service here. The mucoid contents of the bladder simply indicate that there is an obstruction of the cystic duct, and that the gall-bladder has merely become a large retention cyst, the removal of which would not cure the disease. The fact that this man died of an hydatid cyst of the liver, the contents of which obstructed the duct, would never justify you in making such a diagnosis. It is very probable that never again will you see an instance of such

[1] Delivered at the Philadelphia Hospital.

a condition, unless you settle in some country where it is common, as in Australia or Iceland or perhaps northern Minnesota, in our own land.

Pleurisy with Tuberculosis.

I wish now to call your attention to this patient. He is a slight, delicate-looking young man, 20 years old, a stone-cutter by occupation, who has been much exposed to changes in the weather. His ailments in childhood were not unusual, and his habits were not bad. He has used alcohol moderately. There is nothing peculiar in his family history, and we can find but very little about his residence and his associates—an important point to learn in suspected cases of developing tubercular disease. On the thirteenth of July after doing some heavy lifting, he noticed that he was short of breath. About the same time his work was such that he was frequently chilled and wet through. This shortness in the breathing continued, and was attended with a slight amount of coughing, only noticed on stooping. At the time this cough was most severe, he had a pain in his right side, but none in the left. On July 29, he was obliged to quit work, and was admitted to the hospital on August 12, exhibiting these symptoms: great dyspnœa, especially on walking about; respiration increased somewhat, but not greatly—28 to 34 per minute—cough and fever with great depression and prostration.

Here we have a case of a sub-acute illness with the symptoms pointing to some disease of the chest, occurring in a lad who has been so much exposed that we are led to suspect some form of pulmonary disease. Throughout the whole time since his admission he has had fever, and he has also lost flesh to a moderate degree, while he suffers with night-sweats and great prostration. Note, therefore, in the first place, the gradual onset of the disease, and in the second place, the lung symptoms associated with fever, emaciation—not rapid—and night-sweats. We will now proceed to an examination of his chest.

His respirations, you will notice, are hurried, and there is some flatness on the right side of his chest, with fulness on the left. The lower part of the right side expands, while the left base scarcely moves. On palpation there is found a diminution in the vocal fremitus on the left side, with normal fremitus upon the right. On percussion, there is found dulness in the left second interspace, increasing to flatness further down, with tympany over the gastric area. The right side shows normal pulmonary resonance. On auscultation, I find diminution in the breath sounds upon the left side, with a somewhat exaggerated respiratory murmur on the right side, puerile or bronchovesicular in character. We have here a unilateral increase in the size of the chest, which means a unilateral increase in the amount of its contents. Unilateral diminution in movement shows a diminution in the amount of air there, which is also shown by the absence of normal pulmonary resonance. We are able, therefore, from inspection, to eliminate the fact that this enlargement is due to some enlargement of the lung, since, if due to compensatory emphysema—the usual cause of such an enlargement—there would be an increased amount of air, with exaggerated movement of the chest. That it is in the pleura that we have this increase in the contents, is shown by palpation and in the absence of vocal fremitus. There is something here that prevents the vibration of the voice from reaching the hand. Without doubt, this is a pleural effusion.

We must determine now the character of this fluid, and the cause of the effusion. As to the nature of the fluid, we may learn this either by direct exploration, or by a further study of the physical signs. Serum, blood or pus may be present in the chest. If serum, the symptoms are such as you see present in this case; there are no physical signs by which we can determine the presence of blood from serum; but when pus is present we have the sign of Bacelli to rely on, that is, no transmission of the whispered voice. In this case a hypodermic needle has been used for diagnostic purposes, and a small amount of serum has been withdrawn. Such a procedure must be carried out with care, since, unless done antiseptically, empyema will result.

There are general and local causes of pleural effusion. The heart, kidneys and blood are free from disease, and thus the usual causes being eliminated, we are driven back to the pleura itself in investigating as to the cause of this condition. We learn that the disease developed insidiously, with shortness of breath, slight cough and fever.

Therefore, associated with this local symptom of serum in the chest, we have fever, emaciation and night-sweats.

As an aid to our discussion let us ex-

amine a similar case of effusion, with different general symptoms. Here is another well-appearing man who presents similar local symptoms and signs, which are not so marked as in this young man. There is lessened movement of his chest, slight fulness of the intercostal spaces, dulness on percussion, not very high laterally, and posteriorally beginning at the middle of the scapula and ending in flatness at the base, with absent breathing sounds. He has also slight shortness of breath, and slight pain; but otherwise he is not suffering at all. At times you will see such cases presenting no general symptoms; and if you are not careful to examine the patient all over from time to time, such a condition will often be overlooked. It is a very common thing to find cases of pleural effusion developed insidiously. As soon as the effusion takes place all pain disappears, and the patient may not lay much stress upon the slight pain present at first and lasting only a short period. Why, now, is there such a difference in the symptoms of these two cases? It must be due to a difference in the cause or to a difference in the character of the effusion. It is not due to the amount of fluid present; for this will have no effect upon the fever, emaciation and sweats.

Pleurisy with fever, when of long duration, is due to associated complications, to the peculiar nature of the effusion (purulent), or to a difference in the cause. Is there any specific process which is the cause of this condition in this lad? Is there any septic process here? A woman after confinement will have a chill, irregular fever, and a stitch in her side, a true pleurisy due to septicemia or pyemia. There is nothing like this here. There is no suppuration in any part of the body which would cause septicemia. In cases of tuberculosis, which is another true microbic process, pleurisy, like inflammation of other membranes, is apt to occur. Indeed many believe that pleurisy never occurs except of tubercular or septic origin. Is tuberculosis present in this instance? We have not been able in one examination to demonstrate the presence of bacilli in the sputum or serous exudation. It does not follow that tuberculosis is absent. The micro-organisms may be present in small numbers, and be detected only after frequent examinations. There is, however, undoubted tuberculosis at the apex of the right lung. The physical signs—upon which time will not permit me to detail—show this. The co-existence of this process in the right lung, with the fever, emaciation and sweats, are sufficient to warrant a diagnosis of tuberculosis.

The points to remember here are: the ofttimes insidious onset of pleurisy and its association with tuberculosis.

The treatment of the case varies with the cause. In acute pleurisy with effusion the saline treatment is of service; but in this kind, with fever and prostration, we do not use such depletive measures. The fact that tuberculosis is associated with pleurisy does not compel us to make a fatal prognosis. Tubercular disease of serous surfaces is the most favorable form of the disease. Aspiration, or removal of the fluid in tubercular peritonitis, will often cure the disease; and so aspiration of the pleural sac will favor the cure of such cases. This should be done frequently.

COMMUNICATIONS.

CASE OF OVARIOTOMY.[1]

BY JOHN L. ATLEE, M. D.,
CHATTANOOGA, TENN.

Fifty years ago, when the operation for the removal of an ovarian cyst was revived by the late Dr. John L. Atlee, of Pennsylvania, and his associates, and for years and years following their renewal of the operation, the man who was courageous and heroic enough to enter the abdominal cavity with the knife was indeed noted and eminent among his confréres. To-day, with the advance in science and surgery, the doctor who has *not* successfully performed a laparotomy is the one who stands noted among his colleagues. Indeed, so very common are the reports of the operations of laparotomy and ovariotomy, that I would not venture to report this case were it not that there are several features connected with it that I have never known to occur before, and which I think will make the report of interest.

In May, 1889, I was called to see Mrs. L., white, 21 years old, married two years, without issue. She menstruated at the age of fourteen, and continued regular. Directly after her marriage, she noticed an en-

[1] Read before the Tri-State Medical Association, October 16, 1890.

largement in her left side, which gradually increased until it became so considerable as to impede locomotion and interfere with respiration. Because of this preying upon the vital sources of the system, and because of the indigestion, which was a prominent symptom, I found my patient greatly emaciated and weak. Upon examination, I diagnosticated a multilocular cyst of the left ovary, and appointed May 15, two weeks later, as the time for operation. On that day I found her with a pulse of 120, her temperature 103°, and her respiration very rapid, and with these symptoms I thought it best not to operate. Upon her earnest solicitation, and that of her family, for some immediate relief, I performed paracentesis, and drew off thirty pounds of a thick, coffee-colored fluid, albuminous in character, and presenting under the microscope the ovarian germ of Drysdale. The operation gave her great relief. On May 25, ten days afterwards, I operated, being assisted by my son, Dr. James H. Atlee, Dr. Force, of Calhoun, and Dr. Richardson, of Charleston, Tennessee, and removed by abdominal section a tumor weighing forty-five pounds, which in every way confirmed my diagnosis. The pedicle, which was short and thick, I secured with two ligatures, before severing the tumor: using one for each half of the pedicle. The ligatures used were Snowden's iron-dyed black silk ligatures, No. 14. After the tumor was severed, there was a profuse hemorrhage, due to the retraction of the artery from the ligature. Another ligature, cast around the stump, secured the artery and stopped the hemorrhage. After thoroughly cleansing the abdominal cavity with warm carbolized water, the divided edges of the peritoneum were brought together with catgut ligature, and the abdominal wound was closed with the iron-dyed ligature, with a drainage-tube of rubber in the lower portion.

The case progressed without a single unfavorable symptom, with adhesion by first intention. About the eighth week after the operation, symptoms of cystitis appeared, with difficult and painful urination. The urethra was found to be closed with an object, which, upon removal, was identified as one of the ligatures used in ligating the pedicle. Following the removal of the ligature from the urethra there was a flow of bloody pus and urine, with a subsidence of all disagreeable symptoms and a speedy recovery.

About the sixth month after the operation cystitis re-appeared, and gradually increased in severity until the second ligature was passed from the bladder. This ligature I have now in my possession. The passage of this ligature was, in a like manner, followed by a flow of bloody pus and urine, and the rapid abatement of all symptoms of cystitis. Since then my patient has remained in perfect health, and is now a stout, strong, healthy woman, busy with the duties of her household.

The interesting feature of this case is the passage of the ligatures from the peritoneal cavity, through the peritoneum and the walls of the bladder and through the urethra. I have no recollection of an ovariotomy that has progressed just as this one did, with the passage of the ligatures through the walls of the bladder and urethra, at the same time occasioning no inflammation of the peritoneum, no escape of urine into the peritoneal cavity, and no cystitis sufficient to endanger the life of the patient.

CARCINOMA OF THE GALL-BLADDER AND LIVER FROM BILIARY CALCULI.

BY MARIA MITCHELL VINTON, A. M., M. D.,

INSTRUCTOR IN PHYSICAL DIAGNOSIS, WOMAN'S MEDICAL COLLEGE, NEW YORK.

Carcinoma of the liver is, in three-fourths of the cases, secondary, the primary growth occurring in the stomach, intestines, pancreas or mesentery, and being communicated to the liver either by direct extension or by metastasis. Carcinoma of the gall-bladder, extending into the liver, is comparatively rare. Such a carcinoma is the result of the formation of a mass of gall-stones in the gall-bladder, this causing attacks of inflammation and adhesions forming between the liver and the gall-bladder, which become the seat of carcinomatous growth. Carcinoma of the liver is usually nodular, forming a more or less spherical mass protruding from the surface of the liver and changing its shape. When extending from the gall-bladder, it infiltrates the liver substance, giving an even enlargement. The usual form of growth is of the encephaloid type, cell-nests predominating over fibrous tissue.

The following report describes a case of

carcinoma of the gall-bladder extending into the liver, occurring with no previous attacks of biliary colic or other symptoms pointing to the formation of a mass of gall-stones. That a mass of over twelve hundred stones, some of them of considerable size, could form without giving rise to symptoms sufficient to attract the patient's attention, seems almost impossible.

E. M. was seventy-nine years and eleven months old at the time of her death. The family history was very incomplete. Two sisters had died of cancer—in what situation was not known. The patient had had several children who, at the time of her death, were all living and healthy. She could give no history of any past illness more severe than constipation, and had never had biliary colic. She was seen first at the Dispensary of the New York Infirmary for Women and Children, July 2, 1889. She then complained of having had, for about two weeks, nausea, pain and fulness in the stomach after eating. Her tongue was coated and her bowels constipated. Simple gastric remedies relieved her, and no physical examination was made. She came again January 2, 1890. She then complained of the same symptoms as before, but had also a lancinating pain over the liver running through to the back. She stated that she had had this pain for three months, and had not been feeling as well as usual for a year. Examination of the abdomen showed the liver to be enlarged, projecting a finger's breadth and a half below the border of the ribs in the nipple line. The edge was smooth and hard. Below the liver, and attached to it, but separated from it by a sulcus, was a mass the size of a man's fist, which felt distinctly nodular through the lax and thin abdominal wall, and of stony hardness. This mass was tender on pressure, and was the seat of the lancinating pain complained of. The other abdominal organs were normal, as were also the heart and lungs. The urine was stated to be scanty and contained no albumin, but a few granular casts. The patient was thin, but not cachectic. She had simply the look of poor nutrition, so familiar at dispensaries.

A diagnosis was made of carcinoma of the liver, probably secondary to a deposit in the pyloric end of the stomach or duodenum. The patient continued to visit the clinic up to about February 1, when she became unable to leave her house. She frequently located her pain in the epigastrium, instead of over the liver. She had no vomiting and no jaundice. The bowels were constipated throughout her illness. The stools contained, at times, blood and mucus, and were never clay colored.

By February 8, the patient had acquired the cancerous cachexia, was weak and much emaciated. The pain had increased much. On February 13, vomiting occurred for the first time.

The vomited matter contained no blood. The urine showed a small amount of albumin, but no bile pigment. It deposited a very heavy precipitate of urates. The tumor had increased much in size, and was extremely tender. It seemed now to consist of two distinct masses, separated by a deep sulcus. The spleen was of normal size.

On February 20, the patient's temperature was 100.4°. The patient's mind had not been clear for several days, she was delirious during the previous night, and remained in a semi-conscious state. She complained of pain in the epigastrium, but not over the liver. The tumor had been enlarging rapidly, and now reached the umbilicus, and the liver extended down over the lower mass.

February 21, she had marked fever; the skin was slightly jaundiced; but there was now no complaint of pain. Her urine had a specific gravity of 1.029, was dark brown in color, giving a marked yellow froth on shaking, and a play of colors with the sulphuric acid and sugar test. It contained a trace of albumin.

February 22, the temperature was 99.8°, and the woman had severe pain over the liver and was deeply jaundiced.

On February 23, she had a succession of chills, lasting all day, and towards evening became very feverish. She suffered intense pain, so that she cried out and flexed the legs on the abdomen. On February 24, the pain had passed off, but she remained semi-conscious, and died early on the morning of February 25.

An autopsy was made by Dr. Walter Vaught. The lungs showed a few milliary tubercles at the left apex and firm pleuritic adhesions on the right. The heart was normal. The pancreas, spleen and kidneys were normal. The stomach—the suspected seat of primary carcinoma—was normal. The jejunum and ileum were normal. The colon was crowded with hard scybalous masses of feces, but entirely free from carcinoma. The right lobe of the liver projected two finger breadths below the border of the ribs. The

anterior surface of the right lobe over the region of the gall-bladder was of stony hardness; the left lobe was normal in size. Projecting from the lower surface, in the location of an enlarged gall-bladder, was a hard nodular mass, the size of a man's fist, firmly adherent over its entire upper surface to the liver. In cutting into this mass, the gall-bladder was opened and showed the mass to be composed of gall-stones of all sizes, firmly pressed together and forming a single mass, which was not easily broken up until the incision in the gall-bladder had been lengthened. After removing the stones, the walls of the gall-bladder were seen to be infiltrated with cancerous material, which had extended into the substance of the liver. The mass in the liver formed a patch about the size of the palm of a man's hand, varying from one-quarter inch to one and one-half inches in thickness, smooth and not nodular. The substance was firm and of a white or pinkish color on section, contrasting with the deep color of the congested liver tissue. All the bile ducts were in a state of suppuration, and filled with a mixture of pus and bile. The mucous membrane of the gall-bladder was ulcerated in many places. One ulcer had perforated the wall of the duodenum and formed an opening the size of a five-cent piece. In the cystic duct, at its junction with the hepatic, was found a gall-stone, the size of a filbert and firmly impacted. This entirely prevented the passage of bile into the intestine, and as jaundice did not occur until four days before death, the stone must at that time have reached its position at the junction of the ducts, and the severe colic on the day before death was probably due to its attempt to pass down the duct. That the duct must have been partly occluded four days before death is shown by the beginning of jaundice at that time. This caused the suppuration of the bile ducts and the fever and delirium of the last few days. Several inches of the duodenum were included in the cancerous mass, all being firmly matted together. The lumen of the intestine was in one place contracted so as to admit only the tip of the finger. A section of the cancerous mass in the liver showed cell-nests filled with large cells and separated by a more or less scanty stroma. The deposit had occurred by infiltration directly from the adherent gall-bladder.

The gall-stones were of three distinct kinds. There were about a dozen the size of a filbert and of a whitish color. The remainder were of a dark-gray with a yellowish surface easily flaked off by the nail. There were four hundred, varying in size from that of a small French pea to that of a hazel nut. Besides these, there were a large number of smaller ones, like fine granular sand. Of these eight hundred were counted and many were lost. They appeared to consist of cholesterin, variously colored by bile pigment and were very hard.

While years must have been occupied in the formation of this mass of gall-stones, they had produced no biliary colic, and had never caused sufficient irritation to attract the attention of the patient or of any physician, until the growth of the cancer, five months before death.

160 East Thirty-sixth street, New York.

PERISCOPE.

Diabetic Coma.

The *Lancet*, November 8, 1890, says: Dr. R. Schmitz, of Neuenahr, in Germany, has had a large experience in the treatment of diabetes, and therefore his opinion on diabetic coma is to be regarded with interest. He states that under the term "diabetic coma" two distinct conditions are to be recognized, both of them serious and somewhat similar at first glance, but entirely different as regards their pathology, and requiring different modes of treatment. The first is simple collapse, with coma; the second is an auto-infection, and is diabetic coma properly so-called. By most observers it is ascribed to the condition of acetonuria. The collapse is the result of weakened heart power, brought about by an excess of sugar in the blood causing a general degeneration of the muscular tissue throughout the body, in which the heart participates. During collapse there is marked cyanosis, the respiration is quickened, the pulse is generally about 68 to 72 a minute, the temperature is not raised, the heart's beat is almost imperceptible and the first sound can scarcely be heard. The treatment of this condition, according to circumstances, is prophylactic or active. If the cardiac degeneration is recognized before collapse occurs, the patient must be particularly warned against any violent exertion, cardiac depressants (such as the bromides or antypyrin) must be avoided, but in addition to the ordinary diabetic treatment

a little alcohol should be added to the diet, and the patient should be out in the fresh air as much as possible. During the actual attack stimulants must be employed, of which the best are black coffee, castor oil and hypodermic injections of camphor and musk. In true diabetic coma there are generally well-marked prodromal symptoms—complete loss of appetite, somnolence with unrefreshing sleep, etc. The tongue becomes coated and dry, the breath very fetid. When coma sets in there is fever (100° to 102° F.), respiration and pulse are quickened, the former rising to 45 and the latter to 130 a minute. There is much epigastric pain, but there is no tenderness. The diagnosis is easy and is based on the epigastric pain and rise of temperature (both of which are absent in the first form), on a negative result from an examination of the heart, and on the rapidity of the onset of the coma. The treatment is directed to the removal of the toxic material, which Dr. Schmitz considers accumulates in the intestine. He consequently advises frequent doses of castor oil, even if diarrhœa be already present. He orders half an ounce every hour until a full evacuation is produced, and states that he has had excellent results from this method of treatment.

Salinaphthol in Rheumatism.

Salinaphthol is a combination of salicylic acid with naphthol, and is analogous to salol, which is a combination of the same acid with phenol. It is insoluble in water, and has neither odor nor taste.

In a review of salinaphthol, the *Journal de Médecine*, November 9, 1890, says that the remedy seems to act as well as salol in acute articular rheumatism, and it is well borne. In the dose of five and one-half to seven and one-half grains, repeated four times a day, it produces neither headache, ringing in the ears, nor any symptom of poisoning, even after prolonged use. Kobert claims that it is separated into salicylic acid and naphthol by the pancreatic juice and by the ferment which the intestinal mucous membrane secretes, and that this separation is evidenced by the presence of salicylic acid in the urine. Lépine denies that the separation takes place from the action of the intestinal juice, and admits such separation only as the result of the action of the pancreatic juice. There is here room for fresh experiments to examine whether or not the pancreatic juice really has this action, and if it is not the same for salinaphthol as for salol, which is decomposed not only by the pancreatic juice, but also by the alkaline constituents of the blood.

Salinaphthol should be less harmful than salol, since naphthol is less toxic than phenol. But, up to the present time, clinical experience does not seem to have established the efficaciousness of this medicament.

Railway Readers.

The *Lancet*, November 8, 1890, says: a contemporary recently stated that a French medical practitioner has been collecting statistics with regard to those of his patients who complain of nervous affections, and has come to the conclusion that all the evil proceeds from the practice of reading in the train. We can hardly accept this view. Many thousands of business men have no other time than the half or three-quarters of an hour to learn the state of the markets, the last moves in the politics of the great Powers, general news, and the various items that make up the contents of a morning or evening paper, and it would hardly appear that the duration of the cause is sufficient to produce the effects assigned to it, whilst the majority of people travel too rarely and read to little to suffer at all. Our contemporary suggests that a paper with specially large type should be printed for the use of travelers by rail. We fear it would prove of little service. We suggest that all carriages should, as a general rule, be supplied with a better light.

Ergotin in Gleet.

In the Polish periodical, *Wiadomosci Lekarskie*, No. 8, 1890, p. 250, Dr. A. Roicki highly eulogizes ergotin as a means for rapidly curing chronic gonorrhœa. The drug should be simultaneously used, both internally, in pills, and locally, after the following formula.

℞ Ergotini . . . . . 0 3 gramme
Aquæ destillatæ . . . . . 300.0 grammes
M. D. S. Inject a syringeful into the urethra several times a day.

The injections are said to be tolerated perfectly well. The same treatment proves useful in cases of urethral hemorrhage.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE END OF THE YEAR.

A PRIVATE WORD WITH OUR READERS.

During the past year the columns of the REPORTER have contained—as will be seen by looking over the Index and the list of Contributors—a large number of scientific papers of great value from men deservedly eminent in the profession and from many others of less extensive reputation, but who are careful observers and skilful practitioners. The practical value of the papers submitted for publication has always been regarded as the best criterion of their usefulness. Especial attention has been bestowed upon the feature of Clinical Lectures; because it is believed that many readers like to hear what they would be hearing if they were again in the schools where the art of medicine is taught. The Department of Correspondence has covered a large number of American and foreign cities, and has included short communications from readers of the REPORTER in every part of the world. The Selections, Translations and Abstracts have been made with great care, and their source has been fully stated, so that proper credit should be given to those of our contemporaries from which they have been taken, and so that any reader might go at once to the original if he wished. The Editorials and Book Reviews, written by the Editor and a number of men especially competent in various departments of medicine, have always been prepared with an eye single to the good of the reader. No interest, no friendship has been allowed to stand in the way of honest criticism; and no praise has been insincerely uttered.

The purpose of the REPORTER is to be a journal wholly and fearlessly devoted to the advancement of the medical profession, and an alert and conscientious friend to every one who consults its pages. This purpose will shape its policy in the year upon which we are about to enter, and in which we hope all the readers of its pages may be abundantly prospered.

HYSTERIA IN MALES.

In a communication to the *Archives de Médecine*, August, 1890, Dr. A. Souques reports thirteen cases of hysteria in men which he has seen in the Broussais Hospital. From an abstract of this paper in the *Bulletin Médical*, October 1, 1890, we learn that Souques thinks that hysteria in the male is by no means uncommon, that it is encountered frequently in ordinary hospital practice, and that it may be more frequent in the lower classes than hysteria in women. The patients he observed were from twenty to fifty years of age, and were nearly all working men, while some of them were in actual destitution. According to Charcot, such persons are more subject than

others to the causes which sometimes give rise to hysteria, such as traumatism, intoxications and infectious diseases. Souques found the cause of hysteria in his cases to be lead poisoning eleven times, traumatism three times and once each syphilis, dysentery and alcoholism. But there must also be an hereditary nervous tendency.

The symptomatology of hysteria in males is variable. Often the onset is marked by an apoplectiform attack, more often, perhaps, by vertigo, dazzling sensations and a disposition to faint. Vertigo appears to characterize hysteria in the male very much as convulsions do hysteria in women. The most frequent motor troubles of hysteria in males are paralyses, while anæsthesia, limited by the median line of the body, are common. In general demeanor a female hysterical patient is usually gay and lively, while a male is likely to be sombre and gloomy. Hysteria in males is a relatively mild disorder; and usually it terminates favorably. The motor troubles are the most rebellious, and the prognosis in regard to them should be reserved. The patient will probably recover, but it cannot be said at what time. The possibility of relapses should be borne in mind.

The treatment of hysteria in males should be directed to both the hysteria and the provoking cause.

Those who feel interested in the subject of hysteria in men will be interested, we think, to know that Dr. Julius Dreschfeld has an excellent article, "On some of the Rarer Forms of Hysteria in Man" in the *Medical Chronicle*, October, 1890. Dr. Dreschfeld takes almost precisely the same view of the etiology of this disorder as does Souques—who appears to have adopted it from Charcot—and reports four cases which differ from those usually observed after shock and injury. The first two cases belong to the group known as spurious hydrophobia or pseudo-hydrophobia. They are similar to cases familiar to all who have made a thorough investigation of the literature of hydrophobia, and—aside from their intrinsic interest—would prove instructive to persons unfamiliar with the disorders which simulate hydrophobia.

The whole subject of male hysteria is one of great interest, and we think it is one in which there is still room for much investigation. The name is unfortunate; but until a better one is suggested it will have to serve to indicate what is now generally—though vaguely—understood by it.

A KOCH INSTITUTE IN NEW YORK.

In striking contrast to the attitude of caution which all scientific medical men are observing towards the Koch remedy for tuberculosis, it was announced on December 21, that a "New York Bacteriological Institute" had been incorporated for "the study and gratuitous treatment of contagious diseases, comprising a Pasteur and Koch department for the treatment of hydrophobia and tuberculosis." In the list of Trustees, the observant reader will not be surprised to find the names of Drs. Gibier and Liautard.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

CYCLOPÆDIA OF THE DISEASES OF CHILDREN. EDITED BY JOHN M. KEATING, M. D., Volume iv. Large 8vo, pp. xii, 1128. Philadelphia: J. B. Lippincott Company, 1890. Sold by subscription.

It is sometimes hard to find a new thing to say about an admirable book, especially when the space which can be given to a single review is so limited as it is in the REPORTER. It is no small praise to say that the fourth volume of Keating's *Cyclopædia of the Diseases of Children* maintains the high standard of those which preceded it. This volume concludes the work; and the whole Cyclopædia stands a monument of medical, editorial and publishing enterprise and skill, of which American medical men may justly be proud. The present volume contains articles on the ear, the eye, hygiene and diseases of the nervous system. Among them, it would be difficult to select those which are most deserving of commendation; but, in noticing this last volume, we think it is not invidious to call especial attention to the admirable article on physical development by the editor, Dr. Keating, and Dr. J. K. Young.

We call attention to this particular article, because it is a pleasure to add this tribute to the ability which Dr. Keating has displayed in preparing this unusually valuable work.

Special Article.

KOCH'S REMEDY FOR TUBERCULOSIS.

A RESUMÉ OF ITS HISTORY.

A glance over the history of the remedy proposed by Koch for the treatment of tuberculosis (in the strict sense of this term) shows that at the Tenth International Medical Congress, last August, he announced that he had discovered a substance which has the power of preventing the growth of tubercle bacilli, not only in the test-tube, but also in the body of an animal. He also said that guinea-pigs, which are extraordinarily susceptible to tuberculosis, "if exposed to the influence of this substance cease to react to the inoculation of tuberculosis virus, and that in guinea-pigs suffering from *general tuberculosis even to a high degree, the morbid process can be brought completely to a standstill.*"

This announcement created intense excitement and great enthusiasm, and aroused the most sanguine hopes that before long Koch would disclose the character of the "substance" which could arrest the progress of tuberculosis in guinea-pigs, and which he evidently expected would do the same in human beings.

After the Congress had adjourned it came to be believed that Koch had given some of the "substance" to certain practitioners and clinicians of Berlin for experimentation upon their patients, and before long the newspapers began to contain statements that patients with consumption were being treated with Koch's remedy, and then that some of them were cured.

Prompted probably by these imperfect reports, Koch, in a special issue of the *Deutsche Medicinishe Wochenschrift*, dated November 13, 1890, made an announcement which was immediately sent by telegraph to newspapers in various parts of the world.

In this communication Koch refrained from disclosing the nature of his proposed remedy, but indicated what he thought its administration would accomplish. To understand what this communication seemed to promise, certain of its expressions must be carefully weighed. After describing the diagnostic value he attributed to it because of its effect upon persons believed to be tuberculous, Koch said: "Very much more important than the significance which the remedy (*Mittel*) has for diagnostic purposes, is its curative action (*Heilwirkung*)." He then described its employment to cure two cases of lupus, and in the treatment of tuberculosis of the glands, bones and joints, and says "the success was the same as in lupus, rapid recovery (*Heilung*) in fresh and light cases, slowly progressing improvement in severe cases." When speaking of the effect of his substance on consumptives, he said: "The action of the remedy expressed itself in consumptives in general in such a manner that the cough and expectoration usually increased somewhat after the first injections, then, however, became less and less, so that in the more favorable cases they finally disappeared entirely." With loosening of the sputum and the disappearance of bacilli in it, until it too ceased, he says that night-sweats ceased, the appearance improved, and the patients gained in weight. As to the ultimate results, he said: "Patients treated in the incipient stage of phthisis were all freed from every symptom of disease in the course of from four to six weeks, so that they could be regarded as cured." He said also: "Patients with not too large cavities were markedly improved and almost cured. According to those experiences I would assume *that incipient phthisis may be cured with certainty* (Sicherheit) *by the remedy*. This may be partially true also of cases which have not progressed too far."

Koch recognized the limitation necessary to his statements on account of the short period during which the cases he thought cured had been under observation, but he said it might well be assumed that possible relapses would be "*as easily and quickly cured as the first attack.*"

The publication of this announcement produced the most extravagant outburst of applause and raised the most boundless expectations that a cure for consumption had been discovered. The daily papers gave the greatest prominence to the doings and sayings of all connected with the experimental application of the substance to which the newspapers gave the name of "lymph,"[1] and patients and medical men flocked to Berlin to get or to have something from Koch and those to whom he entrusted it.

[1] The word "lymph" is no doubt a misnomer, but is used here as a convenient and now recognized term for what Koch called a "remedy" (Heilmittel).

The first full and authentic accounts of what was being done with the "substance" came in the *Deutsche Medicinische Wochenschrift*, of November 20, 1890, which contains reports of the experiences of Fräntzel and Runkwitz, Levy, Köhler and Westphal.

Fräntzel began to use the "lymph" on September 13, and he and Runkwitz give accounts of four cases of far advanced phthisis, none of which were benefited and two of which ended in death before the report was made; of eight cases of moderately advanced phthisis, in which some improvement was noted.

Levy gives an account of the first three cases of surgical tuberculosis treated by Koch's method—the first a case of lupus injected on October 10.

Köhler and Westphal began their treatment on October 11, on eight patients with tubercular disease of the bones and skin, and four patients without tuberculosis. Their account is most full and complete, but they conclude by saying it is only a contribution of facts, and they do not venture to pronounce a judgment in regard to the value of the remedy.

Von Bergmann's communication was the address he delivered before the Free Surgical Association of Berlin, November 16, 1890. In it he gave the results of his experience and mentions the following application of Koch's remedy, exhibiting the patients to the assembly.

LUPUS—13 CASES.

No. of Patients.	No. of Inoc's.	Dates.
1	5	Nov. 6, 8, 10, 12, 14
1		" 6, 7, etc.
1	1	" 6
5	1	" 16, A. M.
5	1	" 16, Ev'g

CERVICAL ADENITIS—3 CASES.

1	5	Nov. 6, 8, 10, 12, 14
1	1	" 16, A. M.
1	1	" 16, Ev'g

JOINT TUBERCULOSIS—16 CASES.

3	5	Nov. 6, 8, 10, 12 14
1	4	" 6, 10, 12, 14
1	1	" 6
4	1	" 16, A. M.
7	1	" 16, Ev'g

TUBERCULAR LARYNGITIS—4 CASES.

1	4	Nov. 10, 12, 14, 16
3	1	" 16, A. M.

He also showed a man who had been supposed to have tubercular laryngitis, but whom he now believed to have carcinoma of the larynx because he did not react, as was expected, to a single injection of Koch's lymph administered that morning.

It will be noted that only nine of these thirty-seven patients had been under treatment as long as ten days; one had been under treatment for only six days; fourteen had had their first injection on the day of the meeting, and thirteen were injected while the meeting was being held. Careful reading of the address shows that Bergmann felt encouraged to hope that the lymph would prove valuable both in the diagnosis and in the treatment of surgical forms of tuberculosis.

The first person to use Koch's fluid in France was Prof. Péan, who, on November 29, described his experiments in a lecture at the Hospital St. Louis, in Paris. He gave a brief account of his observations in fifteen cases and concluded with the statement that "the results do not permit any conclusion in regard to the curative value of the medicament." (*Bulletin Médical*, November 30, 1890.)

Cornil in a lecture at the Laënnec Hospital, November 30, spoke of having administered the "lymph" to a few patients the day before (November 29) and ventured no opinion whatever in regard to its curative power. (*Bulletin Médical*, December 1, 1890.) In a second lecture (*Bulletin Médical*, December 10, 1890) he said that the reaction indicated by Koch had appeared in every case in which he had used the lymph, and this was especially marked in cases in which the tuberculous process was of relatively recent beginning and active. He found the lymph to produce albuminuria and hematuria.

At the Société Medicale des Hôpiteaux, December 5, communications were made by MM. Ferrand, Cuffer and Thibierge, who had just returned from Berlin where they had studied Koch's method under the auspices of the Berlin medical men. Dr. Thibierge had given especial attention to its effect on lupus, and had carefully examined a number of patients who were said in Berlin to be cured. He said to the Society that in view of his own investigations he felt justified in stating that there had not been a single case of even *apparent* cure of lupus with Koch's "lymph." (*Bulletin Médical*, December 7, 1890.)

M. Cuffer described the effect of the "lymph" on cases of lung disease, and called attention to the fact that the remedy depresses the heart and that it is not reliable as an aid to diagnosis because certain cases of tuberculosis have failed to exhibit the promised reaction after its injection.

M. Debove said that his prosector, M. Rémond, stated that he had seen fourteen cases of undoubted tuberculosis in Berlin, in which the reaction had failed to appear. (*Bulletin Médical*, December 7.)

Dr. Charles Talamon, in the *Médecine Moderne*, December 11, 1890, says: "It seems on reading all that has been published so far, as if the only object of pursuit were to obtain the general and local reaction observed by Koch as a consequence of his injection. The more intense this reaction, the more the experimenters seem to be satisfied." He also makes the interesting suggestion that Koch's "lymph" should be used to determine the real nature of bovine tuberculosis—which has been denied to be of the same nature as tuberculosis in mankind—and also to decide what animals are fit for eating and what are dangerous.

Dr. L. Lereboullet, editor of the *Gazette Hebdomadaire*, says in the issue of December 13, that a patient with hip-disease had just died in coma after receiving his second injection by Péan, and that by December 10, eleven cases of death had occurred in Berlin attributable to this treatment.

On November 24, Köhler made an address in the Hygienic Institute of Berlin (*Wiener Med. Presse*, November 30, 1890), going over his experiences for six weeks. He said absolutely nothing new or justifying the belief that the lymph cures anything.

The special correspondent of the *Wiener Med. Presse*, November 30, quotes the disclaimer of Fräntzel and Bergmann that they had obtained actual cures. Fräntzel said he was "only a tyro," Bergmann said: "We must stick to the point that as yet we have not seen a single case of thorough healing." On November 29, Gerhardt said to him, "Here we can only speak of early effects, but not of curative effects." He also calls attention to the unfortunate appearance of greed of gain in cases of many of the medical men who flock to Berlin, and distinctly contrasts what he calls "*Auri sacra fames*" with the old statement: "*Dat Galenus opes.*"

The *Berliner Klinische Wochenschrift*, December 1, 1890, contains a communication by Israel in regard to the anatomical conditions of two cases of joint tuberculosis treated with Koch's remedy. One specimen was taken from the ankle-joint of a patient who had received thirteen injections in the last eight days before the examination was made. The other patient had received seven injections, the last on November 19. One of these cases gave no anatomical evidence of being tuberculous, and the other was very far from conclusive.

The *Münchener Medinische Wochenschrift*, December 2, contains an interesting article by Grünwald, illustrated, showing the effect of the method upon some of the cases of laryngeal tuberculosis treated by Bergmann already referred to. It also contains a summary of the recent publications in regard to Koch's method. Lublinski thinks that the remedy acts favorably upon laryngeal tuberculosis, although he admits that not a single case of real healing has been observed so far, and lays greatest stress upon the value of the lymph as a means of diagnosis.

The *Wiener Medizinische Wochenschrift*, November 30, contains a description of a chemical and microscopical analysis of the fluid of Koch by the Drs. Jolles, by which it appeared that the active principles were certain albuminoids, probably of the group of tox albumin or enzymes.

The *Berliner Klinische Wochenschrift*, December 8, contains an account of the proceedings before the Prussian Legislature in regard to the attitude of the Government towards the preparation and distribution of Koch's material, when Dr. Von Gossler, the minister of public worship (Cultus Minister) announced that the Government would assume control of the matter, and gave, as the chief reason for maintaining secrecy about its composition, the fact that at an interview with him on November 7, "in the presence of two Councillors of State, it was found that Koch was not able (*im Stande*) to give so exact a description of his process as to insure the preparation of an efficient remedy." Something he could tell but, in the opinion of Gossler, not enough to enable even the most skilful bacteriologist to follow his steps exactly and obtain the material he had obtained.

In the *Berliner Klinische Wochenschrift*, December 2, 1890, is a report of a lecture by Krause, on November 27, in regard to his experiences during two weeks and a half with Koch's method. This communication is also of an uncertain sort, expressing more

of hope than of confidence, and confessing that Krause has seen nothing which he could consider a cure.

The *Deutsche Medicinische Wochenschrift*, December 4, contains a communication by Rosenbach, of Breslau, in regard to his observations on fifty-six patients. Again we find the same unsatisfying conclusions founded upon the short period of observation. Rosenbach distinctly states that he is very far from venturing any conclusions in regard to the therapeutic value of this material. A somewhat similiar communication is published from Gerhardt's clinic by Carl von Noorden, in which—as is generally to be noticed in all the German communications—the cases are reported with thorough fidelity, and in sufficient detail to show the careful manner in which the observations have been made, and the candid scientific spirit of those who have made them; but it leads to the same entirely unsatisfactory result, and does not present any good ground for more than hope in regard to its efficiency.

The *Wiener Medizinische Presse*, December 7, 1890, contains an article by Jacksch, of Prague, who believes the remedy to be of a diagnostic value. He thinks that it is a very valuable expectorant in cases of pulmonary tuberculosis. He does not venture to express an opinion in regard to its value in the treatment of lupus.

[TO BE CONTINUED.]

NOTES AND COMMENTS.

Exact Dosage in the Cataphoretic Use of Drugs.

Dr. Frederick Peterson, in the *New York Medical Journal*, November 15, 1890, says that in a previous paper there are figured two cataphoretic electrodes devised for the anodal diffusion of drugs through the skin. The great drawback until the present moment, however, had been the difficulty of accurately regulating the amount of drug introduced. For this purpose rather complicated electrodes had hitherto been required, and even these had been unsatisfactory. He had recently found, however, that all difficulties are easily obviated by the use of a new and exceedingly simple method. Messrs. Waite & Bartlett have made for him a cataphoretic electrode of metal. Instead of covering it, as before, with sponge, the ordinary metal surface is overlaid with a thin disc of platinum, and around the edge of this is placed a narrow rim of soft rubber. The drug to be used is put drop by drop upon a disc of ordinary tissue paper cut to fit the disc of platinum. Filtering paper or linen cloth may be used instead of tissue paper. A disc two or three centimetres in diameter will hold from one to four drops of the solution. When the medicated disc is placed upon the metal surface of the electrode, and the latter then applied to the skin, it is evident that there is a thin capillary layer of the drug in solution exposed to the cataphoretic power of the anode, between the electrode and the skin, and that the quantity of the drug used may be accurately estimated. The current is allowed to flow if desired until the medicated disc becomes perfectly dry. In this way one may introduce, he says, one or more drops of chloroform, methyl chloride, ether, ten-to-twenty-per-cent. solutions of cocaine, a one-per-cent. solution of helleborin, solutions of iodide of potassium, corrosive sublimate, aconitine—in fact, any drug to be employed in this manner.

To further simplify the method, Dr. Peterson has had medicated cataphoretic discs prepared by a pharmacist for use at any time, for the paper discs may be charged with any amount of a watery solution, and, the water being allowed to evaporate, they may be kept on hand indefinitely. It is only necessary to add two or three drops of water to the disc in administering the drug by electricity.

An apothecary has made for him and is prepared to supply any one with the following cataphoretic discs: Discs of menthol, 2 grains; of helleborin $\frac{1}{25}$ grain; of strythnine nitrate, $\frac{1}{32}$ grain; of iodol, 2 grains; of corrosive sublimate, $\frac{1}{8}$ grain; of cocaine hydrochloride, $\frac{2}{5}$ grain; of aconitine, $\frac{1}{64}$ grain; of potassium iodide, 4 grains; of mercury succinimide, $\frac{1}{4}$ grain; of lithium chloride, 4 grains.

Pleasant Laxative for Infants.

According to the *Revue Générale de Clin. et de Therapeutique*, March 5, 1890, Ferraud uses as a laxative for infants one or two dessert-spoonfuls of the following mixture in a cup of hot milk or weak tea:

℞ Manna . . . . . ʒvi
Magnesiæ Sulphur. loti . . . . . āā ℥iss
Mellis . . . . . f℥vi

Evidences of Criminal Poisoning.

In a paper read before the Medical Jurisprudence Society, of Philadelphia, November 11, 1890, Professor John J. Reese, M. D., read an interesting paper on the subject of "What Constitutes Reliable Evidence in Criminal Poisoning." The evidences he grouped under the heads of those derived from the symptoms before death; those derived from *post-mortem* appearances, especially as regarded the stomach; those obtained from chemical analysis; the evidences obtained by experimenting on living animals; and those derived from the circumstances of the case.

In reference to the evidences derived from the symptoms before death, he said it would be impossible to diagnosticate a case on such symptoms exclusively, as certain diseases presented similar symptoms. An exception might be made in poisoning with strong mineral acids, or with hydrocyanic acid. On the other hand, he had known cases of arsenical poisoning to be mistaken for cholera morbus. The second class of evidences, while strongly suggestive, like the first, could not, he said, be regarded as absolute proof, on account of the resemblance to pathological conditions found in certain diseases. It would not be safe, Dr. Reese said, to found a positive diagnosis on the pathological appearance of the lining of the stomach, as many cases of arsenical poisoning had occurred without leaving any evidence of its action on the lining of that organ.

In reference to evidences derived from chemical analysis, he said there were a number of poisons which could not be recognized by any known chemical tests, and other measures had, therefore, to be resorted to. The presence of a poison in the stomach or other organs did not necessarily mean that death was caused by the poison, as the latter might have been injected after death.

Where there was a failure to detect poisons by chemical analysis, it was necessary sometimes to resort to experiments upon living animals, such as dogs, cats and guinea-pigs. But often the most important evidences were those derived from the circumstances of the case, and, in the majority of cases, the evidence was mainly, if not exclusively, circumstantial. Rarely does it happen that there is direct proof of the administration of the poison.

In conclusion, Dr. Reese spoke of the various circumstances to be considered in a given case; such as the proven purchase and possession of the poison by an accused person; the exercise of an exclusive care of the victim during his illness by the accused; and the existence of a sufficient motive on the part of the accused.

Treatment of Delirium Tremens.

At the Congress of German Naturalists, September 15–19, 1890, Aufrecht, of Magdeburg, made some remarks upon the treatment of delirium tremens, which are reported in *Le Mercredi Medical*, November 5, 1890. Two questions, he said, present themselves: Can the disease be radically cured? Is it useful to continue to give alcohol to patients with delirium tremens?

Aufrecht has treated two hundred and ninety-four alcoholic patients between the years 1880 and 1890, and of this number has lost ten. He treated twenty-two patients with chloral and morphine, and four died; since then he has used chloral alone without any failure. He gives chloral in doses of sixty grains, according to the following formula:

℞ Chloralis . . . . . ʒi
Syrupi
Tinct. Aurantii Am. Cort. . . . āā fʒss
M.

This potion, he says, is well borne by patients. It takes effect the first night, but it should be repeated the next night and the night following, so that repose may be complete. At times, in serious cases, thirty grains of chloral should be prescribed in the morning and the same dose (60 grains?) continued every evening for four or five days.

When one has to deal with all sorts of patients who at the same time are alcoholic, it is necessary to treat them actively. Aufrecht gives six fluid ounces a day of Hungarian wine, or the following potion:

℞ Alcoholis (90 per cent.) . . . . . fʒii
Syrupi . . . . . ♏clx
Tinct. Aromat.
Tinct. Amar . . . . . āā ♏xv
Aq. Amygdale. Amar. . . . . ♏iii
Aq. destill. . . . . fʒviss
Sacchari . . . . . qs.
M.

At times, he says, this treatment does not

stop the delirium. He then prescribes forty-five grains of chloral, and has obtained very good effects from it. He says that patients with alcoholic delirium, who have no other affection, do not need alcohol.

Reduction of Hip Dislocations.

Mr. H. Herbert, Surgeon I. M. S., Acting Civil Surgeon at Aden, writes to the *British Medical Journal*, November 8, 1890: An adult Arab was admitted with an old dorsal dislocation of right hip. He had fallen from a camel quite a month before on the outer side of the limb. Thus the displacement was probably direct, and produced by forcible adduction. Hence, possibly, the failure to reduce it by the orthodox manipulations, based on the assumption of all cases being conversions of primary thyroid dislocations. Manipulations and pulleys were alternately tried for quite an hour under chloroform; but the pulleys were practically of no use, owing to the thigh band being too large. At the end of this time the limb could be abducted freely, though scarcely at all at first; and when the limb was pulled vertically upwards there was considerable movement of the head of the bone grating on the ileum. Still we quite failed with the regular movements; so, while an assistant, seizing the limb below the bent knee, pulled forcibly upwards, with the thigh fully abducted and flexed at rather more than a right angle, I, kneeling on the sound side of the patient, wrapped my arms round the limb near the hip, and, leaning my weight on the inside of the knee, so levered the head of the bone up into the acetabulum. The reduction has been permanent. The great ease with which the bone went in suggests that this method may be of somewhat general application. In old cases it probably needs free preliminary movements to break up adhesions. The extension may, of course, be made with pulleys. The essential thing is the maintenance of full abduction, while the head of the bone is pressed up into position.

Bonducine as a Febrifuge.

Bonduc is said by the *Journal de Médecine*, Oct. 12, 1890, to be the fruit of *Guilandila Bonducella* and of the *Cæsalpinia Bonduc*. The oily cotyledons contain a bitter, resinous principle, which is extracted by alcohol. The alcoholic extract is treated with chloroform, water is added to the chloroform solution, and, after agitation, the inferior layer, which contains the bitter principle, is evaporated and washed with ether and petroleum. A white powder is thus obtained, which is bitter, not acrid, soluble in alcohol, chloroform, acetone, acetic acid, fixed and volatile oils; it is sparingly soluble in ether and sulphide of carbon, and nearly insoluble in water, ether and petroleum.

This bitter principle, called bonducine, is soluble in hydrochloric acid, which it colors rose; with sulphuric acid the acid is an amaranth red, made more perceptible on the addition of a drop of chloride of iron. It is administered with success in intermittent fevers, in the dose of one and two-thirds to two and one-third grains. The powder is given in doses of fifteen or thirty grains a day.

The Quantity of Blood in the Brain.

Professor Roy and C. S. Sherrington (*Journal of Physiology*, vol. xi, p. 85), have examined the influence on the cerebral circulation of stimulation of sensory nerves, of the sympathetic, of voluntary movements, and of the action of drugs. The quantity of blood received by the brain is in proportion to the general blood pressure. They state, also, that the chemical products of cerebral metabolism contained in the lymph which bathes the walls of the arterioles of the brain, can produce variations in the caliber of the cerebral vessels, whence it follows that the brain possesses an intrinsic mechanism by whose aid the quantity of blood is made to vary locally in relation to the local variations of functional activity.—*Glasgow Medical Journal*, October, 1890.

Hydrazoic Acid.

Professor Curtius has recently discovered a body which is gaseous, and which has the formula HN_3. It is made by the interaction of two molecules of hydrazine (N_2H_4) with one of benzoylglycollate. Benzoyl-hydrazine is one of the products, and this on heating with nitric acid is changed to the nitroso compound, which on dehydration is changed to benzoylazoimide, and saponification does the rest.—*Chemist and Druggist*, November 1, 1890.

PHENACETINE-BAYER.

In therapeutic action it is like all the analgesic antithermics, it has a double action—it lowers temperature and soothes pain. The lowering of the temperature is noticeable in cases of pyrexia. In fevers, 7½ grains of Phenacetine lowers the temperature by 1.8° to 3.4° F., and the antithermic action following such a dose lasts four hours. In certain cases the apyrexial period is more prolonged even from the same dose. Phenacetine is thought by some to be superior to antipyrin and acetanilid in producing marked antithermic effects without toxic phenomena. But it is above all as an analgesic that Phenacetine outrivals its predecessor. While it is as powerful, it does not produce pain in the stomach or the scarlatinaform rash of the antipyrin, nor does it give rise to the cyanosis of the acetanilid. However prolonged may be its administration, no bad effect has ever been seen from its use. It has been used for the relief of every form of pain, even for the lightning pain of tabes, with the best results. This double action, as an antithermic and as an analgesic, results from an effect produced upon the spinal cord; and the Phenacetine may be considered a depressor of the excitability of the medulla. The digestive, respiratory, and circulatory systems are not at at all affected by Phenacetine. It is inodorous, it is tasteless, and it is innocuous. [From a paper presented to the Central Kentucky Medical Association, by Steele Bailey, M. D., New England Medical Monthly, March, 1890.]

Phenacetine-Bayer, prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, is supplied by us in ounces and also in the form of our soluble pills and compressed tablets, containing two, four and five grains each. Either form may be obtained of any reputable apothecary.

ARISTOL.

Aristol, a combination of iodine and thymol, manufactured by the Farbenfabriken, formerly Fredr. Bayer & Co., Elberfeld, Germany, is a valuable, inodorous and non-toxic antiseptic remedy, said to be superior to Iodoform, Iodol and Sozo-Iodol.

For further information regarding this new remedy we would refer to the notes we have published, which we will be pleased to mail to applicants.

SULFONAL-BAYER.

WM. H. THOMSON, M. D., LL. D., in speaking of Sulfonal, says:—"Sulfonal is a pure hypnotic, neither anæsthetic nor depressing in character, and it does not affect the heart or circulation, and the sleep it produces is perfect. Being quite insoluble, it requires about three hours to become thoroughly dissolved in the stomach, and should be given about two hours before bed-time. As it is not affected by the digestive secretions, it may be given shortly after the evening meal.

"Sulfonal is of great value in the insomnia of the insane, and the dose should be repeated once during the night if the sleep is too short. **It is specially recommended in cases of nervous insomnia,** also in the sleeplessness of delirium tremens. In the latter case, gr. XX. should be administered every two hours until grs. LX or LXXX have been taken, but it should be remembered that every case of delirium tremens is also a case or starvation, and to produce sleep the patient must be fed. Dose as a hypnotic, gr. XV-XX." [From Notes, Materia Medica, and Therapeutics. Lectures delivered by Prof. Wm. H. Thomson, M. D., LL.D. Edited by Wm. H. McEnroe, M. D.]

Sulfonal-Bayer, prepared by the Farbenfabriken, formerly Fredr. Bayer & Co., Elberfeld, is supplied by us in ounces and in the form of Tablets of 5, 10 and 15 grains, put up in bottles of 10 and 100 tablets each.

We also offer Sulfonal-Bayer in the form of our soluble pills, containing 5 grains each.

W. H. Schieffelin & Co.,

170 & 172 WILLIAM STREET,

NEW YORK.

ESTABLISHED 1855.

DRS. STRONG'S SANITARIUM,

SARATOGA SPRINGS, NEW YORK,

Receives persons recommended to it by their home physicians for Treatment, Change, Rest or Recreation, and places them under well-regulated hygienic conditions so helpful in the treatment of chronic invalids or the overtaxed.

For Treatment: In addition to the ordinary remedial agents, it employs Turkish, Russian, Roman, Sulphur, Electro-Thermal, the French Douche (Charcot's), and all Hydropathic Baths; Vacuum Treatment, Swedish Movements Massage, Pneumatic Cabinet, Inhalations of Medicated, Compressed, and Rarefied Air, Electricity in various forms, Thermo-Cautery, Calisthenics, and Saratoga Waters, under the direction of a staff of educated physicians.

For Change: This Institution is located in a phenomenally dry, tonic, and quiet atmosphere, in the lower arc of the Adirondack Zone, and within the "Snow Belt."

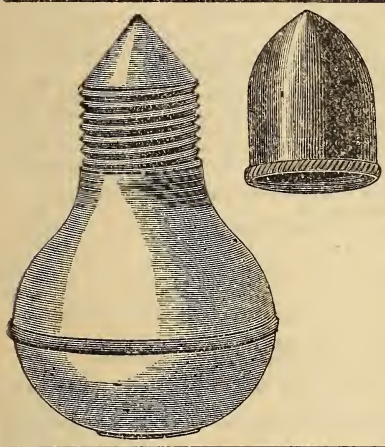
For Rest: The Institution offers a well-regulated, quiet home, heated by steam and thoroughly ventilated, with cheering influences and avoiding the depressing atmosphere of invalidism.

For Recreation: To prevent introspection, are household sports at all seasons of the year, and in Winter, tobogganning, elegant sleighing, etc.; in Summer, croquet, lawn-tennis, etc.

Private professional references furnished upon application. Physicians are invited to inspect the Institution at their convenience. A liberal discount to physicians and their families.

For further information, address,

DRS. S. S. & S. E. STRONG.



THE P.P.P. SYRINGE

Is universally considered the most perfect urethral Syringe in the market, because it combines within itself all desirable qualities. It measures but 1½ x 2¾ inches, has a capacity of fully half an ounce, and is made of one piece of soft rubber with conical point. To protect this soft point and to prevent pocket dust from getting into the Syringe, a Hard Rubber cap screws air-tight over it and enables the patient to carry it in his pocket filled with the injection ordered, ready for use when away from home.

For sale by all druggists.

THE GOODYEAR RUBBER CO.,

49 MAIDEN LANE, NEW YORK.

A Phosphorized Cerebro-Spinant

(FRELIGH'S TONIC).

FORMULA.

Ten minims of the Tonic contain the equivalents (according to the formulæ of the U. S. P., and Dispensatory) of

Tinct. Nux Strychnos,	1 minim.
" Ignatia Amara,	1 "
" Cinchona,	4 "
" Matricaria,	1 "
" Gentian,	½ "
" Columbo,	½ "
" Phosphorus, C. P.,	1-300 gr.
Aromatics,	2 minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

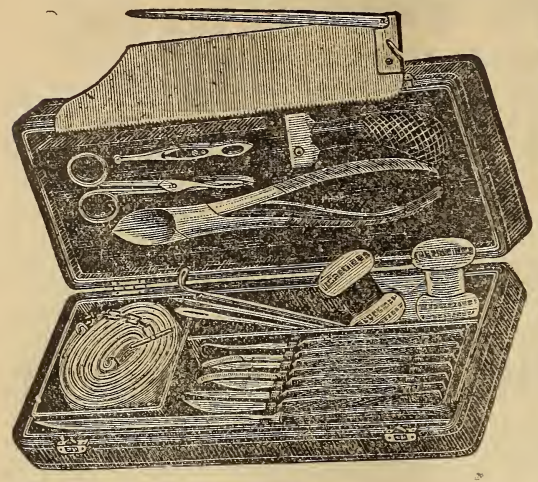
We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

I. O. WOODRUFF & CO.,

Manufacturers of Physicians' Specialties,

No. 88 Maiden Lane, New York City.

LENTZ'S ASEPTIC COMPACT OPERATING SET, No. 10.



We have from time to time made improvements to this set and are now making a perfect aseptic set, which offers especial facilities for aseptic precautions; the blades are soldered into hollow German-silver handles, nickel-plated, are light so as not to be unwieldy and admit of a firm grasp when operating.

The saw is adjusted to the handle on an entirely new principle, being made to separate easily and to facilitate thorough cleansing.

The handle is entirely of metal and fenestrated to overcome unnecessary weight.

Scissors and Forceps having French locks can be separated, and the slide can be easily removed from Artery and Needle Forceps.

Therefore, no opportunity is offered for the lodgment and development of germs.

The entire set is patterned with especial reference to facility in cleansing.

The instruments can be sterilized by placing them in boiling water, without fear of damaging them. Wood or rubber handles will not admit of this procedure. For price, see case A.

The following instruments are put up in either a fine Mahogany or Morocco case, with nickel trimmings, lined with velvet, and has an extra space for Trephine with handle, and Elevator if desired.

One Amputating Knife (6 in. blade); One Finger Knife; One Hernia Knife; One Sharp Curved Bistoury; Two Scalpels; One Tenotome; One Tenaculum; One Pair Scissors, curved or flat; One Saw (9 in. blade); One Liston's Bone Forceps, with Spring; One Artery and Needle Forceps, improved; One Esmarch's Flat Rubber Tourniquet, with Chain; One Hæmostatic Forceps; One Director, with Aneurism Needle; Two Silver Probes; Silk, Wire, Wax and Needles.

With the Sixteen Instruments Contained in this Case, any Ordinary Operation may be Performed.

SIZE, 11 INCHES LONG, 4 INCHES WIDE, 2 INCHES HIGH.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the three Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

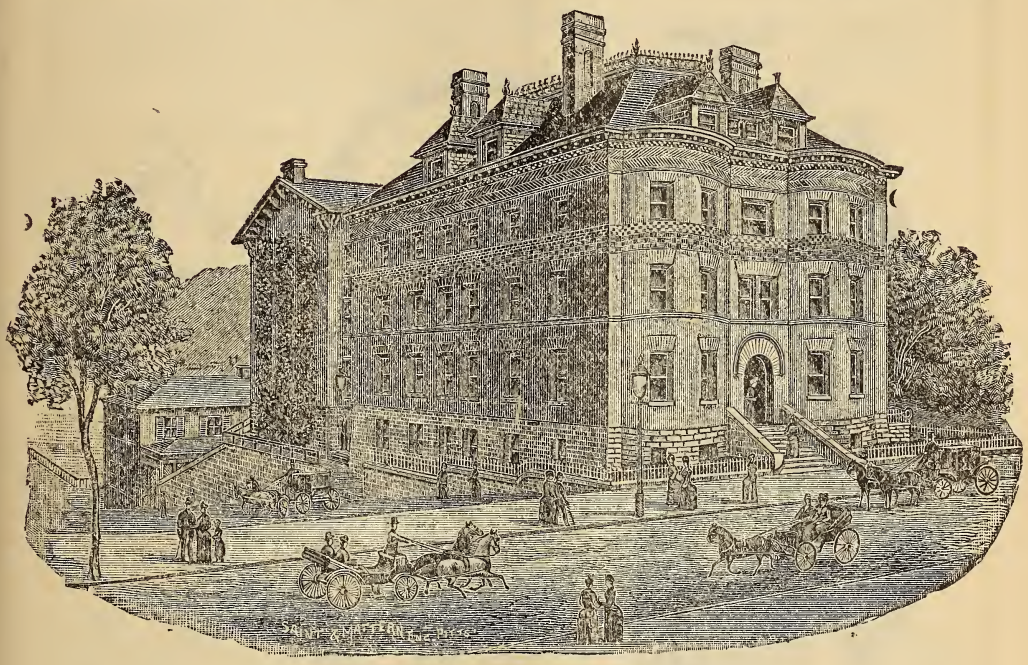
DR. R. S. SUTTON'S

Sanatorium for Diseases of Women.



Seventh Year Opens September 1, 1889.

ALLEGHENY CITY, PA.

This Institution is located on high ground, and overlooks the Allegheny, Monongahela and Ohio rivers; it commands a view of the city of Pittsburgh, and its picturesque surroundings. The building is large and beautiful, it is provided with every modern convenience, the halls are heated by steam, the rooms are commodious, well lighted and ventilated, and heated by open grates. The house is provided with a private parlor and reading-room for patients. The dining-room is large, handsomely finished, and furnished with small tables, securing privacy at meals for those who do not care to have meals served in their own rooms. Patients can be as secluded, should they desire it, as in a well appointed hotel. Each patient is examined by Dr. Sutton, and receives his daily personal attention, while Dr. J. H. Williamson, a physician of ample hospital experience, resides in the Institution, and has, under Dr. Sutton, the immediate care of the patients. The Institution accommodates 25 patients, and is equal in comfort to the best hotels.

Electricity, baths, douches, massage, local treatment, general medication and surgical operations are resorted to according to the requirements of each patient.

For further information address the Matron

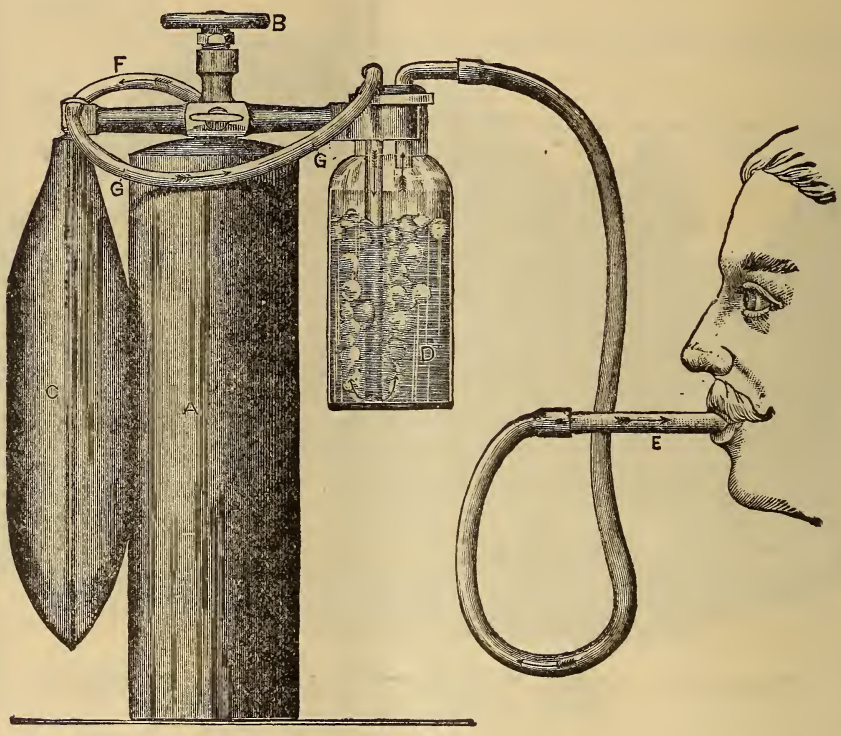
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

To PHYSICIANS.

THE FOREMOST COCOA OF EUROPE
THE COMING ONE OF AMERICA.

VAN HOUTEN'S
"Best and Goes Farthest."

Physicians will do well in recommending, as their European colleagues do, VAN HOUTEN'S COCOA for daily family use. Now that the profession is deprecating the habitual use of alcoholic liquors, and as even tea and coffee are found too exciting for many temperaments—to say nothing of the growing number of cases of nervous disorder in this age of hot haste and feverish anxiety—the question of what beverage may be recommended, as at once refreshing and innocuous, is assuming the highest importance.

VAN HOUTEN'S
Most Appetizing. Easily Digested.

Cocoa has long been known as a useful article of diet, and its claims are steadily winning recognition. Unlike tea or coffee, it is not only a stimulant but a nourisher; and it has the great advantage of leaving none of their narcotic effects on the system. For this reason it is adapted to general use. The strong may take it with pleasure, and the weak with impunity.

VAN HOUTEN'S
The Original—Most Soluble.

"Pure soluble cocoa" is an invention of Mr. C. J. Van Houten, who patented this invention in Holland. Thus all other "pure soluble cocoas" are imitations. The process of manufacturing Van Houten's cocoa is still, to-day, a secret of C. J. Van Houten & Zoon. Chemists and medical men of the highest standing say, universally, that their observation shows that the Van Houtens do exactly what science would suggest for the conversion of raw cocoa into a satisfactory article of food. They simply remove some of the originally contained fat, which is apt to disagree with the system, and in some ingenious manner, increase the solubility of flesh-forming constituents.

VAN HOUTEN'S
"Once Tried, Always Used."

To remove excess of fat is always desirable. Some manufacturers do this by largely diluting the ground cocoa with starch. A cupful of thick beverage may thus be made, which no doubt contains a diminished amount of fat, but of course also contains a diminished amount of every other constituent of the cocoa. For persons who desire a thick, starch-like beverage, such a mixture, miscalled "soluble" cocoa, may be unobjectionable, though the cocoa in it is less easy of digestion than Van Houten's preparation. A far better method, however, is to extract, as the Van Houtens do, one part of the fat from four of cocoa, and, as a consequence, render each of the valuable constituents remaining, one-third more effective than before. Instead of being weakened by starch, Van Houten's cocoa is thus made one-third stronger in every one of its valuable properties.

VAN HOUTEN'S
"Largest Sale in the World."

Requires No Cooking.

Liebig demonstrated that the best substitute for normal human milk was not the milk of any animal, but a combination of animal milk with the elements of those grains which are used in repairing waste, building tissues, and generating heat.

Mellin's Food

Dissolved in hot water and milk, according to the directions, is the genuine Liebig's Food, and promotes in infants a healthy growth, a full development, and a vigorous constitution. *It requires no cooking.*

DOLIBER-GOODALE CO., BOSTON, MASS.

"THIS IS AN AGE OF APOLLINARIS WATER."
—WALTER BESANT.

Apollinaris

"THE QUEEN OF TABLE WATERS."

The filling at the Apollinaris Spring (Rhenish Prussia), amounted to

11,894,000 BOTTLES IN **1887,**
12,720,000 BOTTLES IN **1888** AND
15,822,000 BOTTLES IN **1889.**

"The annual consumption of this favorite beverage affords a striking proof of the widespread demand which exists for table water of absolute purity, and it is satisfactory to find that, wherever one travels, in either hemisphere, it is to be met with; it is ubiquitous, and should be known as the cosmopolitan table water. 'Quod ab omnibus, quod ubique.'"—BRITISH MEDICAL JOURNAL.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

E. FOUGERA & CO., 30 North William St., New York.

Sole Agents for the above Preparations.

GARDNER'S

SYRUP OF HYDRIODIC ACID,

Introduced in 1878 by R. W. GARDNER.

The Reputation which Hydriodic Acid has Attained During the past Eleven Years was Won by this Preparation.

Numerous Imitations prepared differently, and weaker in Iodine, are offered, from the use of which the same therapeutic effects cannot be obtained.

Caution.—Use no Syrup of Hydriodic Acid which has turned red. This shows decomposition and free Iodine. In this state it acts as an irritant and fails to produce desirable results.

Unprincipled apothecaries substitute imitations when Gardner's Syrup is prescribed, and physicians, failing to get desirable and promised results, attribute the fault, unjustly, to Gardner's Syrup.

THERAPEUTIC INDICATIONS.

Hay Fever; Rose Cold; Poisoning by Lead, Mercury or Arsenic; Acute and Chronic Rheumatism; Asthma; Chronic Bronchitis; Catarrh; Congestion of Lungs in Children; Adenitis; Eczema; Lupus; Chronic Malarial Poisoning; Lumbago; Acute Pneumonia; Psoriasis; Scrofulous Diseases; Goitre; Enlarged Glands; Cold Abscesses; Indolent Sores; Excessive Fat; Fatty Degeneration of the Heart; to absorb non-malignant Tumors; and in the latter stages of Syphilis; Syphilitic Phthisis.

Details of treatment furnished physicians upon application to undersigned without charge.

Gardner's Chemically Pure Syrups of Hypophosphites.

Embracing the separate Syrups of Lime, of Soda, of Iron, of Potassa, of Manganese, and an Elixir of the Quinia Salt; enabling physicians to accurately follow Dr. Churchill's method, by which thousands of authenticated cases of Phthisis have been cured. The only salts, however, used by Churchill in Phthisis are those of Lime, of Soda, and of Quinia, and always separately according to indications,—never combined.

The reason for the use of single Salts is because of antagonistic action of the different bases, injurious and pathological action of Iron, Potassa, Manganese, etc., in this disease.

These facts have been demonstrated by thirty years' clinical experience in the treatment of this disease exclusively, by Dr. Churchill, who was the first to apply these remedies in Medical practice. Modified doses are also required in this disease; seven grains during twenty-four hours being the maximum dose in cases of Phthisis, because of increased susceptibility of the patient to their action, the danger of producing toxic symptoms (as hemorrhage, rapid softening of tubercular deposit, etc.), and the necessity that time be allowed the various functions to recuperate simultaneously; over-stimulation, by pushing the remedy, resulting in crisis and disaster.

A pamphlet of sixty-four pages, devoted to a full explanation of these details and others, such as contra-indicated remedies, indications for the use of each hypophosphite, reasons for the use of absolutely pure Salts, protected in Syrup from oxidation, etc., mailed to physicians without charge upon application to

R. W. GARDNER, 158 William St., N. Y. City.

W. H. SCHIEFFELIN & CO., Sole Wholesale Agents, New York.

CELERINA

NERVE TONIC, STIMULANT AND ANTISPASMODIC.

FORMULA.—Every Fluid Drachm represents FIVE grains EACH—Celery, Coca, Kola, Viburnum and Aromatics.

INDICATIONS.—Loss of Nerve-Power (so usual with Lawyers, Preachers, Writers and Business Men), Impotency, Spermatorrhea, Nervous Headache, Neuralgia, Paralysis, Hysteria, Opium Habit, Inebriety, Dyspepsia, and ALL LANGUID conditions of the System.

Indispensable to restore a patient after alcoholic excess.

DOSE.—One or two Teaspoonfuls three or more times a day, as directed by the Physician.

LIQUID IRON-RIO

Palatable and easily assimilated. Does not produce Nausea, nor irritate the Stomach. Does not Cause Headache, nor Constipate. Does not Stain the Teeth. It is so Acceptable to the Stomach that its Use is Admissible when all other forms of Iron would be rejected. Being so Readily Assimilable, it only requires a small Dose.

Each Fluid Drachm contains ONE GRAIN of Iron in a Pleasant and Digestible Form.

DOSE.—One or more Teaspoonfuls as indicated, during or after meals.

S. H. KENNEDY'S

CONCENTRATED EXTRACT OF

PINUS CANADENSIS

DARK. A NON-ALCOHOLIC LIQUID. WHITE.

A MOST VALUABLE NON-IRRITATING MUCOUS ASTRINGENT.

INDICATIONS.—Albuminuria, Diarrhea, Dysentery, Night-Sweats, Hemorrhages, Profuse Expectoration, Catarrh, Sore Throat, Leucorrhea, and other Vaginal Diseases, Piles, Sores, Ulcers, Burns, Scalds, Gonorrhea, Gleet, Etc.

When Used as an Injection, to Avoid Staining of Linen, the WHITE Pinus should be used.

RECOMMENDED BY PROMINENT EUROPEAN AND AMERICAN PHYSICIANS.

RIO CHEMICAL CO., St. Louis, Mo., U. S. A.

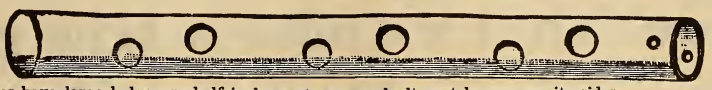
ANTISEPTIC DRAINAGE TUBES.—Glass.



These Tubes have large holes, one-half inch apart, arranged alternately on opposite sides.
They are carefully finished, especial care being taken to make them smooth.
In addition to the drainage-holes, each tube has at one end two smaller holes for the insertion of Safety-Pin, through which it is prevented slipping into the wound.

FURNISHED IN SEVEN SIZES.

No. 1,	$1.25 per doz.	No. 4,	$1.55 per doz.
No. 2,	1.25 "	No. 5,	1.70 "
No. 3,	1.40 "	No. 6,	1.90 "
	No. 7, $2.10 per dozen.		

RAW CAT-GUT. I put this up in coils of 10 feet, four different sizes, Nos. 1, 2, 3, 4 (4 is thickest). Nos. 2 and 3 are the most useful sizes. **No. 1 Coil, 10 Cents; No. 2 Coil, 12 Cents; No. 3 Coil, 14 Cents; No. 4 Coil, 16 Cents.** Full directions with each coil for making it absolutely aseptic.

Three Years' Graded Course. Year begins October 7th, 1890, ends in June, 1891.

FIRST YEAR: Anatomy, Physiology, Chemistry, Histology, Materia Medica.
SECOND YEAR: Anatomy, Physiology, Chemistry, Therapeutics, Pathology, Practice, Surgery, Clinical Medicine and Surgery.
THIRD YEAR: Therapeutics, Practice, Surgery, Children, Clinics, Obstetrics, Gynæcology, Forensic Medicine, Ophthalmology, Hygiene.

An experience of seventeen years has demonstrated that a three years' graded course is superior in every respect to an ungraded, unnatural, and cramming course of two winters. Instead of listening every day from the start to lectures which he cannot comprehend, the student in a graded course utilizes all his time in first mastering the rudiments, and then advancing, step by step, to the higher branches.

Tuition, $80.00 for each Year. Perpetual Ticket, $200.00. Diploma, $25.00.

For circulars with full information, address

Experimental Therapeutics and Physiology—THOMAS J. MAYS, M. D.

Practical individual instruction, Clinical and Demonstrative, to physicians only, during the entire year. Fee for any one branch for six weeks, $15 00; General Ticket for twelve Clinical branches, $100 00; Tickets good for one Clinic weekly for three months, issued on application. For Announcement, with full particulars of CLINICAL AND LABORATORY COURSES, address

S. SOLIS-COHEN, M. D., Secretary.

MEDICO-CHIRURGICAL COLLEGE

OF PHILADELPHIA.

WINTER SESSION will begin Wednesday, October 1st, and continue until April 16th. PRELIMINARY SESSION begins September 8th. SPRING TERM, April 20th, 1891.

The curriculum is graded, and a preliminary examination and three Annual Winter Sessions are required. Laboratory instruction in Chemistry, Histology, Pathology, Hygiene, Physiology, with Bedside instruction in Medicine, Surgery and Gynecology, is a part of the regular course.

Fees: Matriculation $5.00. First and second years, each $75.00. Third year $100.00. Fourth year free to those in attendance three sessions; to all others $100.00.

For Announcement or information apply to

E. E. MONTGOMERY, M. D.,

1818 Arch Street, Philadelphia, Pa.

THE JEFFERSON MEDICAL COLLEGE

OF PHILADELPHIA.

The 66th Annual Session of the Jefferson Medical College begins October 1st and continues nearly 7 months. Preliminary Lectures will be held from 22d of September.

EACH student is immediately and personally taught in Obstetrics and Gynæcology, Physical Diagnosis, Laryngology, Ophthalmology, Medical Chemistry, Pharmacy, Materia Medica, and Experimental Therapeutics, Histology and Experimental Physiology, Minor Surgery, Bandaging, Operations on the Cadaver, Pathology, Neurology, and Electro-Therapeutics.

Three annual regular sessions are required. Bedside instruction in Medicine, Gynæcology, Surgery and Obstetrics is a part of the third year course. No extra fee.

The **Annual Announcement** will be sent on application to **J. W. HOLLAND, M. D., Dean.**

NATIONAL MEDICAL COLLEGE.

MEDICAL DEPARTMENT OF THE

COLUMBIAN UNIVERSITY,

WASHINGTON, D. C.

The 68th Annual Session will begin October 7th and end March 1st. Graded three years' course required. Women admitted. Professors: J. F. Thompson, W. W. Johnston, A. F. A. King, E. T. Fristoe, Wm. Lee, D. W. Prentiss, D. K. Shute.

For circulars, address

A. F. A. KING, M. D., DEAN, 726 THIRTEENTH ST., N. W., WASHINGTON D. C.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 125TH ANNUAL WINTER SESSION will begin Wednesday, October 1st, 1890, at 12 M., and will continue seven months. The PRELIMINARY SESSION begins September 22d, 1890, the Spring Term early in May, 1891.

The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D., LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.

ESTABLISHED 16 YEARS. BEWARE OF IMITATIONS.

COLDEN'S LIQUID BEEF TONIC

AN INVALUABLE AID IN MEDICAL PRACTICE.

ORIGINAL | COLDEN'S LIEBIG'S LIQUID EXTRACT OF BEEF AND TONIC INVIGORATOR. | LABEL.

ESSENTIALLY DIFFERENT FROM ALL OTHER BEEF TONICS. UNIVERSALLY ENDORSED BY LEADING PHYSICIANS.

This preparation, consisting of the Extract of Beef (prepared by Baron Liebig's process), the best Brandy obtainable, soluble Citrate of Iron, Cinchona and Gentian is offered to the Medical Profession upon its own merits. It is of inestimable value in the treatment of **Debility, Convalescence from Severe Illness Anæmia, Malarial Fever, Chlorosis, Incipient Consumption, Nervous Weakness,** and maladies requiring a Tonic and Nutrient. It is quickly absorbed by the Stomach and upper portion of the Alimentary Canal, and therefore finds its way into the circulation quite rapidly.

COLDEN'S LIQUID BEEF TONIC appeals to the judgment of intelligent Physicians in the treatment of

ALL CASES OF GENERAL DEBILITY.

By the urgent request of several eminent members of the medical profession, I have added to each wineglassful of this preparation two grains of Soluble Citrate of Iron, and which is designated on the label, **"With Iron, No. 1;"** while the same preparation, **Without Iron,** is designated on the label as **"No. 2."**

In prescribing this preparation, physicians should be particular to mention *"COLDEN'S;"* viz., *"Ext. Carnis Fl. Comp. (Colden)."* A Sample of **COLDEN'S BEEF TONIC** will be sent free on application, to any physician (enclosing business card) in the United States. *Sold by druggists generally.*

C. N. CRITTENTON, General Agent, 115 Fulton St., New York.

GLENN'S SULPHUR SOAP.

BEWARE OF COUNTERFEITS.

Physicians know the great value of the local use of Sulphur in the **Treatment of Diseases of the Skin.**

Constantine's Pine-Tar Soap.

THE BEST SOAP MADE.

Has been on trial among physicians for very many years as a healing agent. **By far the Best Tar Soap made.**

Wholesale Depot, C. N. CRITTENTON, 115 Fulton St, New York.

Samples of above Soaps SENT FREE, on application, to any Physician enclosing card.

CLEARANCE SALE

MEDICAL AND SURGICAL REPORTER,

P. O. Box 843, Philadelphia, Pa.

FELLOWS'
HYPO-PHOS-PHITES

(SYR: HYPOPHOS: COMP: FELLOWS)

Contains **The essential elements** to the Animal Organization—Potash and Lime.

The **Oxydizing Agents**—Iron and Manganese;

The **Tonics**—Quinine and Strychnine,

And the **Vitalizing Constituent**—Phosphorus,

Combined in the form of a Syrup, with *slight alkaline reaction.*

It Differs in Effect from all others, being pleasant to taste, acceptable to the stomach, and harmless under prolonged use.

It has Sustained a High Reputation in America and England for efficiency in the treatment of Pulmonary Tuberculosis, Chronic Bronchitis, and other affections of the respiratory organs, and is employed also in various nervous and debilitating diseases with success.

Its Curative Properties are largely attributable to Stimulant, Tonic, and Nutritive qualities, whereby the various organic functions are recruited.

In Cases where innervating constitutional treatment is applied, and tonic treatment is desirable, this preparation will be found to act with safety and satisfaction.

Its Action is Prompt; stimulating the appetite and the digestion, it promotes assimilation, and enters directly into the circulation with the food products.

The Prescribed Dose produces a feeling of buoyancy, removing depression or melancholy, and hence is of great value in the treatment of MENTAL AND NERVOUS AFFECTIONS.

From its exerting a double tonic effect and influencing a healthy flow of the secretions, its use is indicated in a wide range of diseases.

Prepared by JAMES I. FELLOWS, Chemist,

48 VESEY STREET, NEW YORK.

Circulars sent to Physicians on Application.

FOR SALE BY ALL DRUGGISTS.

MILK OF MAGNESIA.

A PURE HYDRATED OXIDE OF MAGNESIUM.—(MgH_2O_2.)

ANTACID AND CORRECTIVE.

Especially recommended in the Gastro-intestinal irritations of infant, child and adult life—Nausea—Vomiting in Pregnancy—Sour Stomach—Diarrhœa—Cholera Infantum—and the Rheumatic and Gouty conditions resulting from acid secretions.

This Hydrate presents Magnesia practically in solution without grittiness or precipitation—No danger from concretions as with the calcined—Free from Carbonic Acid—Miscible with other fluids—in a form easy of administration and absorption. Superior to lime water or chalk mixture for addition to milk. It is not a purge: but in antacid, corrective or mild laxative indications will be found reliable and safe. It combines well with Syrup Rhubarb—Soda—Opium—the various astringents, etc.

PHOSPHO-MURIATE OF QUININE,

COMPOUND,

A RELIABLE ALTERATO-CONSTRUCTIVE,

Particularly indicated in conditions of **disturbed nutrition** and **tissue retrograde.**

An easily appropriated general tonic, promoting digestion, and safe under prolonged use. A permanent combination of the soluble Wheat Phosphates, with Muriate of Quinine, Iron and Strychnia.

Of greater strength than the various Hypophosphite compounds.

The above are put up in Dispensing and Trade Containers.

DIGESTIBLE COCOA.
WHEAT PHOSPHATES.
COD LIVER OIL EMUL.

THE CHAS. H. PHILLIPS CHEMICAL CO.,
77 PINE STREET, NEW YORK.

CH. MARCHAND'S

Peroxide of Hydrogen,

MEDICINAL (ABSOLUTELY HARMLESS)

H_2O_2

is rapidly growing in favor with the medical profession. It is the most powerful antiseptic known, almost tasteless, and odorless. Can be taken internally or applied externally with perfect safety. Its curative properties are positive, and its strength and purity can always be relied upon. This remedy is not a nostrum.

Experiments of Prof. Pasteur, Dr. Koch, and many other scientific authorities, prove beyond doubt that Germs, Bacteria, or Microbes cause and develop: **NOSE, THROAT, AND LUNG DISEASES—Diphtheria, Croup, Sore Throat, Catarrh of the Nose, Hay Fever, Bronchitis, Laryngitis, Pharyngitis, Whooping Cough, Consumption and other Chronic Affections, specific or not.**

GERMS, BACTERIA, OR MICROBES are instantaneously annihilated when brought into contact with **Ch. Marchand's Peroxide of Hydrogen.** This wonderful bactericide acts both chemically and mechanically upon all excretions and secretions, so as to thoroughly change their character and reactions instantly. By destroying the microbian element this remedy removes the cause of the disease.

CAUTION.—I would earnestly impress upon the profession the very great importance of prescribing only my Peroxide of Hydrogen (Medicinal), from which all hurtful chemicals have been eliminated.

By specifying in your prescriptions "Ch. Marchand's Peroxide of Hydrogen (Medicinal)," which is sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing my label and signature, you will never be imposed upon.

Prepared only by

Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

A book containing full explanations concerning the therapeutical applications of Ch. Marchand's Peroxide of Hydrogen (Medicinal), with opinions of the profession, will be mailed to physicians free of charge on application.

¼ lb. bottle, retail, 35 cents; ½ lb. bottle, retail, 50 cents; 1 lb. bottle, retail, 75 cents.

THE P.P.P. SYRINGE

Is universally considered the most perfect urethral Syringe in the market, because it combines within itself all desirable qualities. It measures but 1½ x 2¾ inches, has a capacity of fully half an ounce, and is made of one piece of soft rubber with conical point. To protect this soft point and to prevent pocket dust from getting into the Syringe, a Hard Rubber cap screws air-tight over it and enables the patient to carry it in his pocket filled with the injection ordered, ready for use when away from home.

For sale by all druggists.

PIL. PHENACETINE ET SALOL, 5 GRS., "W. H. S. & CO."

{Phenacetine-Bayer, ... 2½ grs.}
{Salol, ... 2½ grs.}

Anti-Rheumatic and Analgesic. This combination was first suggested by Dr. M. F. Price, Colton, Cal., President of the "Southern California Medical Society." In an address to the members he says: "In a case of acute Rheumatism, affecting elbows, wrists, knees, and ankles, ordered Phanacetine and Salol every three hours. No local application ordered. Made five daily visits, found the patient each day improved, discharged with orders to continue the medicine three times a day for a week."

After citing other cases, one of Sciatica where the patient was suffering such pain that the slightest motion caused faintness with nausea and continuous vomiting; two with acute Rheumatism, and one with Neuralgia of the stomach, Dr. Price continues:

"It will be observed that in some of these cases I have combined Salol with Phanacetine. I did this on the principle of the well-known effect of Salicylic Acid in Rheumatism, but I rely on the Phenacetine for the relief of the pain, and in this way perhaps the cure of the disease causing it." (*Southern California Practitioner*, August, 1889.)

PIL. TERPIN HYDRAT., 2 GRS., "W. H. S. & CO.,"

A new and potent remedy in the treatment of coughs, catarrh, bronchitis, and kindred diseases.

Terpin Hydrate is indicated in cases where violent irritation of the bronchial mucous membrane exists, and where the secretion is inconsiderable and peculiarly viscid, such as is met with in the chronic catarrh accompanying emphysema and phthisis. The effect obtained is always an increase and a liquefaction of the secretion, a considerable reduction of the irritation, and easy expectoration.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced in their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to maintain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

The continued favor which has been shown to our **Soluble Pills** is sufficient evidence that care has been bestowed upon their manufacture.

As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and they invite the most critical examination and test, either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque, nor insoluble, but elastic, thin, transparent, and readily soluble.

For further information about them we refer to our formula books and price lists, which we shall be happy to furnish upon application.

W. H. Schieffelin & Co.,

NEW YORK.

Glycones

Contain 95 per cent. Pure Glycerin.

Made in both Adult and Infant Sizes.

FOR THE IMMEDIATE RELIEF OF CONSTIPATION.

Glycones are incomparably superior to the glycerin suppositories on the market, inasmuch as the covering is impervious to moisture, unchangeable and easily removed, preserving the Glycones in all climates. The constitution of the Glycones is so modified as to cause no irritation of the rectum.

The value of Glycones in Constipation is well established, painless and copious stools being promptly produced. The Glycerin acts by lubrication and solution of the indurated feces and by stimulating the bowel, thus providing a certain and agreeable method of emptying the colon at pleasure.

After inserting, the Glycone should be retained as long as possible in order to obtain the best results.

Glycones. These invaluable "peristaltic persuaders" are prepared in a most excellent and improved manner by Messrs. Eli Lilly & Co., of Indianapolis. Their Glycones contain 95 per cent. of glycerin, and a beauty of their construction is the peculiar water-proof covering of each Glycone, which is readily and easily removed. By simply pressing upon or slightly squeezing the Glycone between the fingers it slips out with astonishing ease, leaving the covering between the fingers. A great improvement, as any one will readily recognize who has ever made the effort to divest one of the ordinary Suppositories from its lead foil and tissue-paper envelope.—*Medical Practitioner*, Oct., 1889.

FOR SALE BY ALL DRUGGISTS.

Price, 35c. per box (one doz. Glycones), sent by mail.

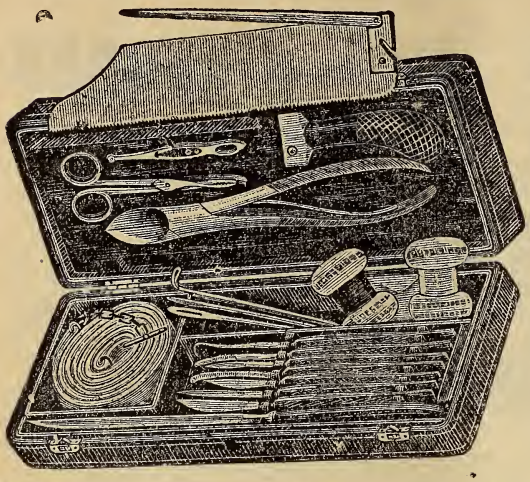
LENTZ'S ASEPTIC COMPACT OPERATING SET, No. 10.



We have from time to time made improvements to this set and are now making a perfect aseptic set, which offers especial facilities for aseptic precautions; the blades are soldered into hollow German-silver handles, nickel-plated, are light so as not to be unwieldy and admit of a firm grasp when operating.

The saw is adjusted to the handle on an entirely new principle, being made to separate easily and to facilitate thorough cleansing.

The handle is entirely of metal and fenestrated to overcome unnecessary weight.

Scissors and Forceps having French locks can be separated, and the slide can be easily removed from Artery and Needle Forceps.

Therefore, no opportunity is offered for the lodgment and development of germs.

The entire set is patterned with especial reference to facility in cleansing.

The instruments can be sterilized by placing them in boiling water, without fear of damaging them. Wood or rubber handles will not admit of this procedure. For price, see case A.

The following instruments are put up in either a fine Mahogany or Morocco case, with nickel trimmings, lined with velvet, and has an extra space for Trephine with handle, and Elevator if desired.

One Amputating Knife (6 in. blade); One Finger Knife; One Hernia Knife; One Sharp Curved Bistoury; Two Scalpels; One Tenotome; One Tenaculum; One Pair Scissors, curved or flat; One Saw (9 in. blade); One Liston's Bone Forceps, with Spring; One Artery and Needle Forceps, improved; One Esmarch's Flat Rubber Tourniquet, with Chain; One Hæmostatic Forceps; One Director, with Aneurism Needle; Two Silver Probes; Silk, Wire, Wax and Needles.

With the Sixteen Instruments Contained in this Case, any Ordinary Operation may be Performed.

SIZE, 11 INCHES LONG, 4 INCHES WIDE, 2 INCHES HIGH.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the three Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the three Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux,* Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic,* is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence,* having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases. Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

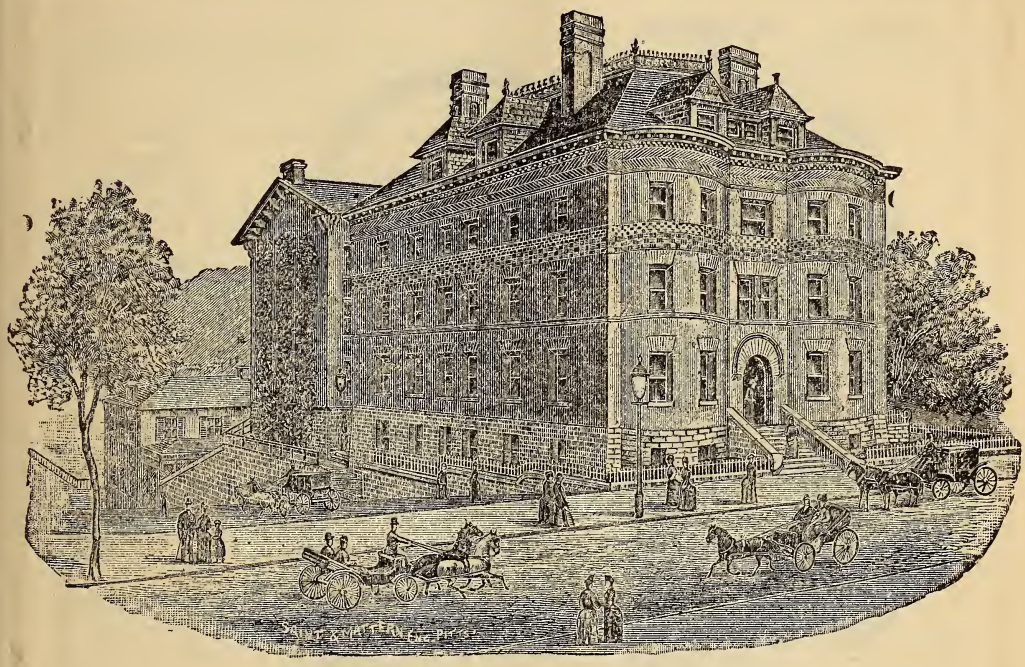
DR. R. S. SUTTON'S

Sanatorium for Diseases of Women.



Seventh Year Opens September 1, 1889.

ALLEGHENY CITY, PA.

This Institution is located on high ground, and overlooks the Allegheny, Monongahela and Ohio rivers; it commands a view of the city of Pittsburgh, and its picturesque surroundings. The building is large and beautiful, it is provided with every modern convenience, the halls are heated by steam, the rooms are commodious, well lighted and ventilated, and heated by open grates. The house is provided with a private parlor and reading-room for patients. The dining-room is large, handsomely finished, and furnished with small tables, securing privacy at meals for those who do not care to have meals served in their own rooms. Patients can be as secluded, should they desire it, as in a well appointed hotel. Each patient is examined by Dr. Sutton, and receives his daily personal attention, while Dr. J. H. Williamson, a physician of ample hospital experience, resides in the Institution, and has, under Dr. Sutton, the immediate care of the patients. The Institution accommodates 25 patients, and is equal in comfort to the best hotels.

Electricity, baths douches, massage, local treatment, general medication and surgical operations are resorted to according to the requirements of each patient.

For further information address the Matron

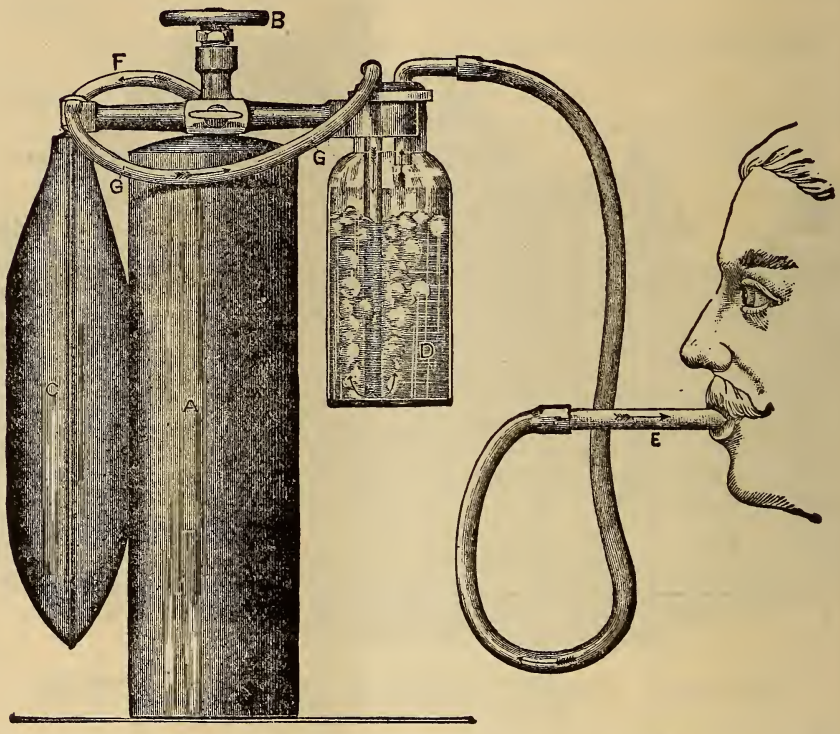
170 Ridge Ave., Allegheny, Pa.

INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC. PROPHYLACTIC. DEODORANT.

LISTERINE

NON-TOXIC. NON-IRRITANT. NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request.

LAMBERT PHARMACAL CO., ST. LOUIS, MO.

GENOIS'

Diastasic Extract of Malt,

A PURE LIQUID EXTRACT OF MALT.

CONTAINING at least 12 per cent. of extractive matter, rich in nitrogenous principles, and less than 4 per cent. of alcohol for its preservation. It is recommended for the treatment of dyspepsia, defective nutrition, flatulence, etc., as well as for a tonic. It is also recommended to persons suffering from insomnia. Its sedative and soporific action is gentle and gradual. Generally prescribed by physicians. It is now the standard malt in the market. Over 300 gross sold in Philadelphia last year. Obtainable from the retail drug trade.

GASTRIC DERANGEMENTS.

HORSFORD'S ACID PHOSPHATE.

Unlike all other forms of phosphorus in combination, such as dilute phosphoric acid, glacial phosphoric acid, neutral phosphate of lime, hypophosphites, etc., the phosphates in this product are in solution, and readily assimilative by the system, and it not only causes no trouble with the digestive organs, but promotes in a marked degree their healthful action.

In certain forms of dyspepsia it acts as a specific.

Dr. H. R. MERVILLE, Milwaukee, Wis., says: "I regard it as valuable in the treatment of gastric derangements affecting digestion."

Send for descriptive circular. Physicians who wish to test it will be furnished a bottle on application, without expense, except express charges.

Prepared under the direction of Prof. E. N. HORSFORD, by the

Rumford Chemical Works, Providence, R. I.

Beware of Substitutes and Imitations.

CAUTION:—Be sure the word "HORSFORD'S" is PRINTED on the label. All others are spurious. NEVER SOLD IN BULK.

A Phosphorized Cerebro-Spinant

(FRELIGH'S TONIC).

FORMULA.

Ten minims of the Tonic contain the equivalents (according to the formulæ of the U. S. P., and Dispensatory) of

Tinct. Nux Strychnos,	1 minim.
" Ignatia Amara,	1 "
" Cinchona,	4 "
" Matricaria,	1 "
" Gentian,	½ "
" Columbo,	½ "
" Phosphorus. C. P.,	1-300 gr.
Aromatics,	2 minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

I. O. WOODRUFF & CO.,

Manufacturers of Physicians' Specialties,

No. 88 Maiden Lane, New York City.

"THIS IS AN AGE OF APOLLINARIS WATER."
—WALTER BESANT.

Apollinaris

"THE QUEEN OF TABLE WATERS."

The filling at the Apollinaris Spring (Rhenish Prussia), amounted to

11,894,000 BOTTLES IN **1887,**
12,720,000 BOTTLES IN **1888** AND
15,822,000 BOTTLES IN **1889.**

"The annual consumption of this favorite beverage affords a striking proof of the widespread demand which exists for table water of absolute purity, and it is satisfactory to find that, wherever one travels, in either hemisphere, it is to be met with; it is ubiquitous, and should be known as the cosmopolitan table water. 'Quod ab omnibus, quod ubique.'"—
BRITISH MEDICAL JOURNAL.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the **HUNGARIAN APERIENT WATER SOLD BY THE COMPANY** from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

E. FOUGERA & CO., 30 North William St., New York.

Sole Agents for the above Preparations.

GOUDRON DE BLOUNT

PREPARED FROM THE GENUINE CAROLINA TAR.

DOSE.—One fluid drachm four or more times a day (as indicated), either full strength, diluted, or, in combination.

INDICATIONS.—Chronic and acute affections of the Air Passages, Coughs, Colds, Bronchitis, Asthma and Consumption.

WILLIAM MURRELL, M.D., F.R.C.P.,

Lecturer on Pharmacology and Therapeutics at the Westminster Hospital; Examiner in Materia Medica to the Royal College of Physicians of London; Fellow of the Medico-Chirurgical College of Philadelphia,

Says:—"I have used with success 'Goudron de Blount.' The results have been good, and the preparation is popular with patients."

Clinical Notes sent on Application. ST. LOUIS, MO.

REASONS FOR SPECIFYING FAIRCHILD'S PEPSIN.

It is the most active, gives the greatest value for the price asked.

One grain will digest more albumen than will a grain of any other pepsin made. We do not care by whose test, what the proportions of albumen, water, and acid, only let the conditions be the same for all.

It is positively guaranteed to be permanent. It will not get soft or sticky, or deteriorate in value, because it is not a peptone. It is free from all the well-known characteristics of peptone. It is not made by a patented or pirated process.

If you prescribe pepsin in scale or powder, and it becomes sticky, you may be sure that it is not Fairchild's. Investigate the matter, place the blame where it belongs.

There are pepsins "made to sell" under the title of scales—products which are inferior and dissimilar to Fairchild's pepsin in scales. They are peptones made by a patented process and sold under cover of a title first and properly used only by Fairchilds to describe their original, true pepsin in the form of scales.

The druggist is told "they are just as good as Fairchild's. If Fairchild's is not specified, put in mine." But claims and pretensions, however colossal, cannot make peptones permanent.

There is no soluble or peptone pepsin equal in activity to Fairchild's, none which will keep in all weathers and all conditions as Fairchild's will.

FAIRCHILD BROS. & FOSTER, NEW YORK.

ALETRIS CORDIAL

UTERINE TONIC AND RESTORATIVE.

Prepared from the Aletris Farinosa or True Unicorn and Aromatics.

INDICATIONS.

Amenorrhea, Dysmenorrhea, Leucorrhea, Prolapsus Uteri, Sterility, to Prevent Miscarriage, Etc.

DOSE:—ONE TEASPOONFUL THREE OR FOUR TIMES A DAY.

UNRIVALED AS A UTERINE TONIC IN IRREGULAR, PAINFUL, SUPPRESSED AND EXCESSIVE MENSTRUATION.

It Restores Normal Action to the Uterus, and Imparts Vigor to the Entire Uterine System.

☞Where women have miscarried during previous pregnancies, or in any case where miscarriage is feared, the ALETRIS CORDIAL is indicated, and should be continuously administered during entire gestation.

CHAS. CLAY, M. R. C. S., Manor House, Dewsbury, England, says:—I find Aletris Cordial (Rio) is of great service in threatened miscarriage.

FRANCIS E. CANE, L R. C. S., &c., Leeds, England, says:—I have tried the Aletris Cordial (Rio) in two cases of long standing dysmenorrhea, with excellent results. One of these patients has spent a week in bed every month for two years. After all the usual remedies, I put her on Aletris Cordial, and for the last two periods she has been out and about all the time.

L. M. WATSON, M. D., Delhi, Ills., says:—I have used Aletris Cordial (Rio) in cases of dysmenorrhea. suppressed menses and threatened miscarriage, and also, combined with Celerina, as a tonic after confinement, with the happiest results, and now I am using it on a case of leucorrhea, with injections of S. H. Kennedy's Extract of Pinus Canadensis, and it is acting like a charm.

P. H. OWEN, M. D., Morganville, Ala., says:—I have prescribed Aletris Cordial (Rio) in several cases with the most satisfactory results, and regard it as the best uterine tonic I have met with in a professional experience of over twenty-five years. In cases of threatened miscarriage it acts like a charm. Would recommend its continuous administration in all cases when there is any indication of miscarriage.

Dr. W. BERTHELOT, Santander, Spain, says:—I have tried the Aletris Cordial (Rio), and it has seemed to me to be useful, especially in cases of dysmenorrhea.

Dr. RASQUINET, Jupile, near Liege, Belgium, says:—I tried Aletris Cordial (Rio) in the case of a woman who had had several miscarriages at the end of five months, and who is now again pregnant, having reached the seventh month. thanks to Aletris Cordial.

R. REECE, M. R. C. S., Walton-on Thames, England, says:—Aletris Cordial (Rio) in painful menstruation is most valuable. A wife of a minister suffered much, and had had three miscarriages. I prescribed Aletris Cordial. She has for the first time, gone her full time, and was safely confined with a male child.

J. T. COLLIER, M. D., Brooks, Me., says:—I have used your Aletris Cordial (Rio) in cases of females at the menopause. Consider it one of the finest remedies for these cases.

Dr. GORDILLON, St. Amand, France, says: I have tried the Aletris Cordial (Rio) in a case of dysmenorrhea. The result I obtained from the use of your preparation was excellent, better than I had obtained in the same patient by prescribing the usual remedies employed in such cases.

W. F. TOOMBS, M. D., Morrillton, Ark., says:—I have used a great deal of your Aletris Cordial (Rio) and I find it all you claim for it in amenorrhea, dysmenorrhea, metritis, leucorrhea; I don't think it has an equal. I have used it in two cases of threatened miscarriage and the trouble was obviated. For a general Uterine Tonic I know of nothing superior.

R. D. PATTERSON, L. R. C. S. &c., Medical Officer, Caledon Dispensary, Co. Tyrone, Ireland, says:—I have very great pleasure in testifying to the very high opinion I hold of Aletris Cordial (Rio) in threatened miscarriage.

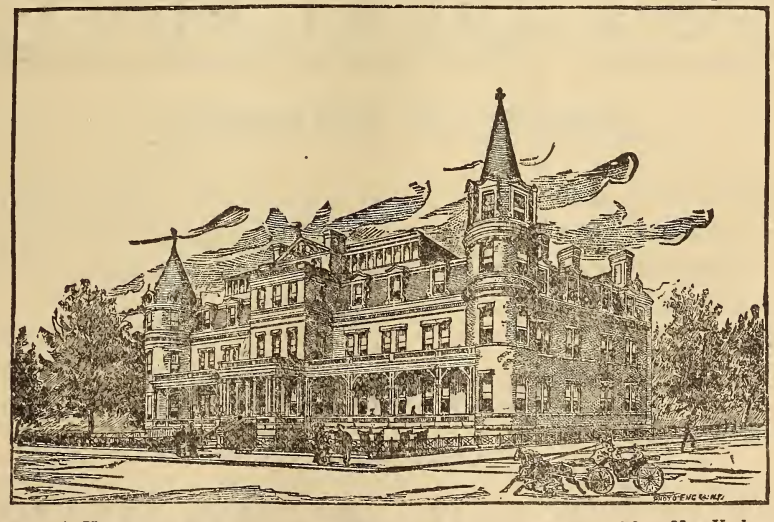
DR. WILLIAM A. HAMMOND'S SANITARIUM,

FOR DISEASES OF THE NERVOUS SYSTEM, Washington, D. C.



Dr. William A. Hammond announces to the medical profession that he has returned from New York to Washington, D. C., where he has established, in a building especially erected for the purpose, a *Sanitarium* for the treatment of mild and curable cases of mental derangement, diseases of the nervous system generally, cases of the morphia and chloral habits, and such other affections as may properly be treated by the remedial agencies under his control.

The *Sanitarium* is situated on Columbia Heights, at the corner of Fourteenth Street and Sheridan Avenue. The position is the highest in the immediate vicinity of Washington, the soil is dry, and all the surroundings are free from noxious influences. Electricity in all its forms, baths, douches, massage, inhalations, nursing, etc., are provided as may be required by patients, in addition to such other medical treatment as may be deemed advisable.

A large *Solarium* for sun-baths and exercise in cold or inclement weather and heated with steam in winter, is constructed on the top of the main building.

The *Sanitarium* has now been in successful operation since the 7th of January, 1889.

For further information Dr. Hammond can be addressed at The Sanitarium, Fourteenth Street and Sheridan Avenue, Washington, D. C.

Doctor.—Three days' trial will prove that we offer a true galactagogue which greatly increases the quantity of mother's milk, notably improves the quality and removes the maternal debility due to Lactation, Nutrolactis.

UNG. DIACHYLI.

DIACHYLON OINTMENT.

MADE from the recipe of a celebrated dermatalogist. Years of experience devoted to preparing this ointment have led to the production of a non-irritating application which is now largely prescribed by physicians in all parts of the country.

Made by

JOHN OGDEN,

SUCCESSOR TO

STRYKER & OGDEN,

Corner Walnut and Thirteenth Streets,

PHILADELPHIA, PA.

☞Samples furnished on application.

GLYCOZONE

Is used as an internal remedy, or for local dressings. It is absolutely harmless; and Ozone is its healing agent.

GLYCOZONE, by its wonderful antiseptic and healing properties, not only prevents the fermentation of the food in the stomach, but it quickly cures the inflammation or irritation of the mucous membrane. It is a specific for disorders of the stomach: **Dyspepsia, Catarrh of the Stomach, or Gastritis, Ulcer of the Stomach, Heart-Burn.** Sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing CHAS. MARCHAND'S label and signature.

Prepared only by Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

A book containing full explanations concerning the therapeutical applications of GLYCOZONE, with opinions of the profession, will be mailed to physicians free of charge on application.

UNIVERSITY OF MARYLAND
SCHOOL OF MEDICINE.

Eighty-fourth Annual Announcement, 1890–91. The next regular session will begin October 1st, 1890. A full course of didactic lectures, with ample clinical and dissecting-room facilities.

FACULTY:

GEORGE W. MILTENBERGER, M. D.,
Emeritus Professor of Obstetrics, and Honorary President of the Faculty.
CHRISTOPHER JOHNSON, M. D.,
Emeritus Professor of Surgery.
SAMUEL C. CHEW, M. D.,
Professor of Principles and Practice of Medicine and Hygiene.
FRANK DONALDSON, M. D.,
Emeritus Clinical Professor of Diseases of the Throat and Chest.
WILLIAM T. HOWARD, M. D.,
Professor of Diseases of Women and Children and Clinical Medicine.
JULIAN J. CHISOLM, M. D.,
Professor of Eye and Ear Diseases.
FRANCIS T. MILES, M. D.,
Professor of Physiology and Clinical Professor of Diseases of Nervous System.
LOUIS McLANE TIFFANY, M. D.,
Professor of Surgery.
J. EDWIN MICHAEL, M. D.,
Professor of Obstetrics.
I. EDMONSON ATKINSON, M. D.,
Professor of Materia Medica and Therapeutics, Clinical Medicine and Dermatology.
R. DORSEY COALE, PH. D.,
Professor of Chemistry and Toxicology.
JOHN NOLAND MACKENZIE, M. D.,
Clinical Professor of Diseases of the Throat and Nose.

Professor of Anatomy.

Demonstrator of Anatomy.

For catalogue and further information, address: **Dr. I. E. ATKINSON, Dean, 605 Cathedral Street.**

DENTAL DEPARTMENT.

Ninth Annual Announcement. Next regular session begins October 1st, 1890. New and excellent Infirmary and Laboratory, with abundance of clinical material.

FACULTY:

FRED. J. S. GORGAS, M. D., D.D. S.,
Professor of Principles of Dental Science, Dental Surgery, and Dental Mechanism.
JAMES H. HARRIS, M. D., D.D. S.,
Professor of Operative and Clinical Dentistry.
I. EDMONSON ATKINSON, M. D.,
Professor of Materia Medica and Therapeutics.
FRANCIS T. MILES, M. D.,
Professor of Physiology.
L. McLANE TIFFANY, M. D.,
Clinical Professor of Oral Surgery.

Professor of Anatomy.
R. DORSEY COALE, PH. D.,
Professor of Chemistry.
JOHN C. UHLER, M. D., D.D. S.,
Demonstrator of Mechanical Dentistry.
CHAS. L. STEEL, M. D., D.D. S.,
Demonstrator of Operative Dentistry.

Demonstrator of Anatomy.
AND EIGHT ASSISTANT DEMONSTRATORS.

For catalogue and other information, apply to **Dr. F. J. S. GORGAS, Dean, 845 Eutaw Street, Baltimore.**

Philadelphia Polyclinic and College for Graduates in Medicine.

THE POLYCLINIC HOSPITAL, NORTHWEST CORNER BROAD AND LOMBARD STS.

PROFESSORS:

Emeritus Professor of Surgery—R. J. LEVIS, M. D.
Emeritus Professor of Diseases of the Throat—J. SOLIS-COHEN, M. D.
Emeritus Professor of Diseases of the Ear—CHARLES H. BURNETT, M. D.
Emeritus Professor of General and Orthopædic Surgery, CHARLES B. NANCREDE, M. D.
Applied Anatomy and Operative Surgery—JOHN B. ROBERTS, M. D.
Diseases of the Mind and Nervous System—CHARLES K. MILLS, M. D.
Clinical Chemistry and Hygiene—HENRY LEFFMANN, M. D.
Diseases of the Skin—ARTHUR VAN HARLINGEN, M. D.
Diseases of the Eye—GEORGE C. HARLAN, M. D.
Genito-Urinary and Venereal Diseases—J. HENRY C. SIMES, M. D.
Gynæcology—B. F. BAER, M. D.
Operative Surgery—LEWIS W. STEINBACH, M. D.
Diseases of the Chest—THOMAS J. MAYS, M. D.
Diseases of Throat and Nose—ALEXANDER W. MACCOY, M. D.
Orthopædic Surgery—H. AUGUSTUS WILSON, M. D.
Diseases of the Eye—EDWARD JACKSON, M. D.
Clinical Medicine and Applied Therapeutics—SOLOMON SOLIS-COHEN, M. D.
Diseases of the Mind and Nervous System—S. WEIR MITCHELL, M. D., LL. D.
Diseases of the Ear—B. ALEX. RANDALL, M. D.
Obsetrics and Diseases of Children—EDW. P. DAVIS, M. D.
Orthopædic Surgery—THOMAS G. MORTON, M. D.
Clinical Surgery—THOMAS S. K. MORTON, M. D.
Experimental Therapeutics and Physiology—THOMAS J. MAYS, M. D.

Practical individual instruction, Clinical and Demonstrative, to physicians only, during the entire year. Fee for any one branch for six weeks, **$15 00**; General Ticket for twelve Clinical branches, **$100.00**; Tickets good for one Clinic weekly for three months, issued on application. For Announcement, with full particulars of CLINICAL AND LABORATORY COURSES, address

S. SOLIS-COHEN, M. D., Secretary.

MEDICO-CHIRURGICAL COLLEGE

OF PHILADELPHIA.

WINTER SESSION will begin Wednesday, October 1st, and continue until April 16th. PRELIMINARY SESSION begins September 8th. SPRING TERM, April 20th, 1891.

The curriculum is graded, and a preliminary examination and three Annual Winter Sessions are required. Laboratory instruction in Chemistry, Histology, Pathology, Hygiene, Physiology, with Bedside instruction in Medicine, Surgery and Gynecology, is a part of the regular course.

Fees: Matriculation $5.00. First and second years, each $75.00. Third year $100.00. Fourth year free to those in attendance three sessions; to all others $100.00.

For Announcement or information apply to

E. E. MONTGOMERY, M. D.,

1818 Arch Street, Philadelphia, Pa.

THE JEFFERSON MEDICAL COLLEGE

OF PHILADELPHIA.

The 66th Annual Session of the Jefferson Medical College begins October 1st and continues nearly 7 months. Preliminary Lectures will be held from 22d of September.

EACH student is immediately and personally taught in Obstetrics and Gynæcology, Physical Diagnosis, Laryngology, Ophthalmology, Medical Chemistry, Pharmacy, Materia Medica, and Experimental Therapeutics, Histology and Experimental Physiology, Minor Surgery, Bandaging, Operations on the Cadaver, Pathology, Neurology, and Electro-Therapeutics.

Three annual regular sessions are required. Bedside instruction in Medicine, Gynæcology, Surgery and Obstetrics is a part of the third year course. No extra fee.

The **Annual Announcement** will be sent on application to **J. W. HOLLAND, M. D., Dean.**

NATIONAL MEDICAL COLLEGE.

MEDICAL DEPARTMENT OF THE

COLUMBIAN UNIVERSITY,

WASHINGTON, D. C.

The 68th Annual Session will begin October 7th and end March 1st. Graded three years' course required. Women admitted. Professors: J. F. Thompson, W. W. Johnston, A. F. A. King, E. T. Fristoe, Wm. Lee, D. W. Prentiss, D. K. Shute.

For circulars, address

A. F. A. KING, M. D., DEAN, 726 THIRTEENTH ST., N. W., WASHINGTON D. C.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 125TH ANNUAL WINTER SESSION will begin Wednesday, October 1st, 1890, at 12 M., and will continue seven months. The PRELIMINARY SESSION begins September 22d, 1890, the Spring Term early in May, 1891.

The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D., LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.
JAMES TYSON, M.D., Professor of Clinical Medicine.
HORATIO C. WOOD, M.D., LL.D., Professor of Materia Medica, Pharmacy and General Therapeutics.
THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry and Toxicology.
JOHN ASHHURST, JR., M.D., Professor of Surgery and of Clinical Surgery.
EDWARD T. REICHERT, M.D. Professor of Physiology.
WILLIAM F. NORRIS, M.D., Honorary Prof. of Ophthalmology
BARTON COOKE HIRST, M.D., Professor of Obstetrics.
J. WILLIAM WHITE, M.D., Professor of Clinical Surgery.
JOHN GUITÉRAS, M.D., Professor of General Pathology and Morbid Anatomy.
GEORGE A. PIERSOL, M.D., Professor of Histology and Embryology.
SAMUEL G. DIXON, M.D., Professor of Hygiene.

DR. JAMES TYSON, Dean,
36th and Woodland Avenue, Philadelphia.

Requires No Cooking.

Liebig demonstrated that the best substitute for normal human milk was not the milk of any animal, but a combination of animal milk with the elements of those grains which are used in repairing waste, building tissues, and generating heat.

Mellin's Food

Dissolved in hot water and milk, according to the directions, is the genuine Liebig's Food, and promotes in infants a healthy growth, a full development, and a vigorous constitution. *It requires no cooking.*

DOLIBER-GOODALE CO., BOSTON, MASS.

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

GENUINE BLAUD'S PILLS.

These pills, which have been inserted in the new French Pharmacopœia, have been employed with the greatest success for more than fifty years by most French and foreign physicians, to cure anemia, chlorosis, and all chlorotic affections in which iron is indicated.

Here is the opinion of men most eminent in medical science who have employed them.

"For thirty-five years, in which I have practised medicine, I have recognized the incontestable advantages of BLAUD'S PILLS over all other ferruginous preparations, and I regard them as the best anti-chlorotic."—DR. DOUBLE, *Ex-President of the Academy of Medicine.*

"Of all the ferruginous preparations, which have given good results in the treatment of chlorotic affections, BLAUD'S PILLS appear to us to deserve to hold the first rank."—*Dictionnaire universel de médecine*, Vol. II, p. 99.

These pills, prepared according to the genuine formule of the originator, by his nephew, Aug. Blaud, Pharmacist of the Faculty of Paris, are sold only in bottles of 200 pills and half bottles of 100 pills, at a cost of 5 and 3 francs ($1.00, and seventy-five cents), and never in smaller quantities. *See that his name is stamped on each pill.* PARIS, 8 RUE PAYENNE, and at every Pharmacy. (Beware of imitations.)

BLAUD

A HOME TREATMENT

For Catarrh, Deafness, Throat, and Lung Affections, that will *cure.*

A new apparatus that has received the highest award, is giving universal satisfaction, and is just the thing for the busy practitioner. Special inducements to

ONE PHYSICIAN

in every city, town, and village. A 24-page pamphlet, giving full instructions, terms, etc., sent free. Address

Moore-McGregor Medication,

351 West 7th St., P. O. Box 671, CINCINNATI, O.

"What a boon it would be to the Medical Profession if some reliable Chemist would bring out an Extract of Malt in combination with a well-digested or peptonized Beef, giving us the elements of Beef and the stimulating and nutritious portions of Ale."—J. MILNER FOTHERGILL, M.D.

Ale & Beef

"PEPTONIZED"

(EXTRACT:—BOVIS CUM MALTO.)

's the identical combination suggested by the late eminent Fothergill.

EACH BOTTLE REPRESENTS 1-4 POUND OF LEAN BEEF THOROUGHLY PEPTONIZED.

It is the only Mild Stimulant combined with a Perfect Food known. It is very palatable, aids digestion, is retained by the most delicate stomach, and the purity of its ingredients is guaranteed.

THE "PEPTONIZED" BEEF

is manufactured by Prof. Preston B. Rose, of Chicago, late of the faculty of the University of Michigan.

THE ALE USED IS THE PUREST AND BEST MADE IN AMERICA

Especially brewed for this purpose, and guaranteed to be equal to the best imported ales, as only the best Canada Malt and the choicest new hops are used in its manufacture.

IT IS A REAL FOOD; NOT A MERE STIMULANT,

as it contains all the albumen and fibrine of the beef as well as the nutritive qualities of the malted barley.

It is most useful during the period of Gestation, in allaying all vomiting, and invaluable to Nursing Mothers; also in Typhoid Fever and Dysentery.

Prof. G. A. Leibig says: "A careful chemical examination of the Peptonized Ale and Beef shows a much larger per cent. of nitrogenous blood and muscle-making matter over all other malt extracts, and that it is also rich in Diastase, giving it the power to digest Starch Foods."

PREPARED BY

The Ale and Beef Company,

DAYTON, OHIO, U. S. A.

Two full-sized bottles will be sent FREE to any physician who will pay express charges. Please mention this journal.

A CASE WITH A LESSON IN IT.

We have frequently referred to the necessity of keeping the pregnant woman supplied with those chemical substances which she must give to the child in the formation of its little frame, and the dire effects which may result from a deficiency of those substances. The headaches, neuralgias, spinal tenderness, and some of the many disorders of digestion, and even mental failure, may be all prevented or relieved by supplying to the mother the chemical food her system demands.

We have noticed a few cases where the most serious results have occurred to the mother by such a deficiency, one of which is well worth relating. Mrs. M., aged 30, pregnant with her third child, suffered from the second to the fifth month of her pregnant term with gradually failing strength and health, and nervous irritability. She was very restless nights for three or four days, the peculiar restlessness of complete nervous exhaustion, and was irrational for more than a week.

At this time I advised that she have a teaspoonful of Murdock's Liquid Food every hour in milk, and a little wine every four hours. The third night she had fifteen drops of hydrobromic acid dil. every three or four hours, which was continued for a week. The liquid food after a week every two hours, and all other medicines were discontinued. Her bowels were moved with a mild laxative at first, and afterward became regular. Her tongue cleaned quickly and her skin assumed a more natural appearance.

At this writing, less than three weeks from our first visit, the patient is able to sit up an hour at a time, is quite rational and cheerful, has a good appetite, the bowels are quite regular, there is no headache, and but little spinal tenderness. She sleeps reasonably well if fed frequently. She is allowed to suit her taste in her diet. The child is quite active, and the mother is progressing so nicely that it is hoped that she will pass safely through her confinement, which is nearly at hand. She will be kept on the liquid food and the phosphates until her confinement after which, the condition will suggest the treatment. This is the most marked case of a starved nervous system we have ever seen, and the benefit derived from the treatment proves the theory as to the cause of the trouble.

Apropos with the above, comes the question of the selection of nutritious foods for those many cases which demand strong and immediate nourishment. The food used in the above case has produced marvelous results for us in some of those extreme cases in which we have used it.

In one case of nervous exhaustion the insomnia was absolutely painful. When the exhaustion forced the patient to sleep there was an immediate sense of falling or approaching death, or there were hallucinations which were appalling, rendering the nights unbearable. One teaspoonful of Murdock's Liquid Food so nourished the system the first night it was given that the patient sank into a quiet, refreshing sleep which lasted, with a single awakening, until morning, and the improvement the patient obtained was most striking.

One case of mitral regurgitation with leucocythemia and nervous exhaustion improved more rapidly on this food than on all other measures combined. In cases of nervous exhaustion and brain tire, its effects are most marked, as we have experienced many times in the past five years in the frequent personal use of the agent. It contains the principles of pure, healthy blood and nerve tissue ready for immediate assimilation. Fourteen per cent. of the entire quantity is uncoagulated albumen, as we have demonstrated by actual analysis.

We have tided babies over critical periods often with a few drops in its usual diet. We have given it to dipsomaniacs with or without non-alcoholic stimulants with superb results. The sole objection our patients have to it is its odor. Its taste is not disagreeable; it has the odor and appearance of blood. All objections are soon forgotten, however, in the results of its action upon the nutrition of the system, and the patient soon learns to like it, and often craves for it, drinking it from the bottle or a glass readily, like any beverage. It ought to be the food par-excellence for rapid appropriation in all conditions of exhaustion.

P. S.—Phosphates act well with the Liquid Food.

Editorial of the Chicago *Medical Times*, June, 1890.

Doctor:

You find the hot weather very exhaustive to your consumptive patients, don't you?

Have you ever thought of the reason why?

It is simply because the salts of the tissues are wasted in excessive perspiration.

How can you restore this waste? By administering quinine, iron, strychnine, manganese and all the range of exciting tonics? Not at all.

That only increases the difficulty and hastens the end.

There is but one way to give permanent improvement, and that is to restore the waste to the tissues by administering the hypophosphites of lime and soda, *chemically pure*. This will not only restore the waste but will also check most of it by restoring sufficient tone to the tissues to restrain the unnecessary perspiration. By this means you can make this a season of grateful refreshment to these afflicted ones, and, by taking advantage of the freedom from colds which the season brings, start them on the way to permanent recovery.

These are clinical facts, not theory.

McArthur's Syrup of Hypophosphites is the only one in the market consisting of the *chemically pure* hypophosphites of lime and soda.

If there is special indication for any other medicinal agent it can easily be added to the prescription.

What are the other conditions requiring the remedy, and which are rapidly cured by it? Scrofulosis, Rachitis, Chronic Cough, Chronic Bronchitis, Chronic Alcoholism, Impotence, Spermatorrhea, Nervousness, General Debility, Brain Exhaustion, Loss of Memory, Chronic Diarrhœa, Teething, Summer Diarrhœa, Suppurating Discharges, and Sores, Uterine Fibroids and all disorders of waste or faulty nutrition.

See that you get that which is absolutely pure and genuine. Write your prescriptions thus:

Syr: Hypophos: Comp: McArthur. One Bottle.

A large bottle will be sent you free (excepting express charges) if you will send your professional card or letter head. Address,

McARTHUR HYPOPHOSPHITE CO.,

PHENACETINE-BAYER.

In therapeutic action it is like all the analgesic antithermics, it has a double action—it lowers temperature and soothes pain. The lowering of the temperature is noticeable in cases of pyrexia. In fevers, 7½ grains of Phenacetine lowers the temperature by 1.8° to 3.4° F., and the antithermic action following such a dose lasts four hours. In certain cases the apyrexial period is more prolonged even from the same dose. Phenacetine is thought by some to be superior to antipyrin and acetanilid in producing marked antithermic effects without toxic phenomena. But it is above all as an analgesic that Phenacetine outrivals its predecessor. While it is as powerful, it does not produce pain in the stomach or the scarlatinaform rash of the antipyrin, nor does it give rise to the cyanosis of the acetanilid. However prolonged may be its administration, no bad effect has ever been seen from its use. It has been used for the relief of every form of pain, even for the lightning pain of tabes, with the best results. This double action, as an antithermic and as an analgesic, results from an effect produced upon the spinal cord; and the Phenacetine may be considered a depressor of the excitability of the medulla. The digestive, respiratory, and circulatory systems are not at at all affected by Phenacetine. It is inodorous, it is tasteless, and it is innocuous. [From a paper presented to the Central Kentucky Medical Association, by Steele Bailey, M. D., New England Medical Monthly, March, 1890.]

Phenacetine-Bayer, prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, is supplied by us in ounces and also in the form of our soluble pills and compressed tablets, containing two, four and five grains each. Either form may be obtained of any reputable apothecary.

ARISTOL.

Aristol, a combination of iodine and thymol, manufactured by the Farbenfabriken, formerly Fredr. Bayer & Co., Elberfeld, Germany, is a valuable, inodorous and non-toxic antiseptic remedy, said to be superior to Iodoform, Iodol and Sozo-Iodol.

For further information regarding this new remedy we would refer to the notes we have published, which we will be pleased to mail to applicants.

SULFONAL-BAYER.

Wm. H. Thomson, M. D., LL. D., in speaking of Sulfonal, says:—"Sulfonal is a pure hypnotic, neither anæsthetic nor depressing in character, and it does not affect the heart or circulation, and the sleep it produces is perfect. Being quite insoluble, it requires about three hours to become thoroughly dissolved in the stomach, and should be given about two hours before bed-time. As it is not affected by the digestive secretions, it may be given shortly after the evening meal.

"Sulfonal is of great value in the insomnia of the insane, and the dose should be repeated once during the night if the sleep is too short. It is specially recommended in cases of nervous insomnia, also in the sleeplessness of delirium tremens. In the latter case, gr. xx. should be administered every two hours until grs. lx or lxxx have been taken, but it should be remembered that every case of delirium tremens is also a case or starvation, and to produce sleep the patient must be fed. Dose as a hypnotic, gr. xv-xx." [From Notes, Materia Medica, and Therapeutics. Lectures delivered by Prof. Wm. H. Thomson, M. D., LL.D. Edited by Wm. H. McEnroe, M. D.]

Sulfonal-Bayer, prepared by the Farbenfabriken, formerly Fredr. Bayer & Co., Elberfeld, is supplied by us in ounces and in the form of Tablets of 5, 10 and 15 grains, put up in bottles of 10 and 100 tablets each.

We also offer Sulfonal-Bayer in the form of our soluble pills, containing 5 grains each.

W. H. Schieffelin & Co.,

170 & 172 William Street,

NEW YORK.

ESTABLISHED 1855.

DRS. STRONG'S SANITARIUM,

SARATOGA SPRINGS, NEW YORK,

Receives persons recommended to it by their home physicians for Treatment, Change, Rest or Recreation, and places them under well-regulated hygienic conditions so helpful in the treatment of chronic invalids or the overtaxed.

For Treatment: In addition to the ordinary remedial agents, it employs Turkish, Russian, Roman, Sulphur, Electro-Thermal, the French Douche (Charcot's), and all Hydropathic Baths; Vacuum Treatment, Swedish Movements Massage, Pneumatic Cabinet, Inhalations of Medicated, Compressed, and Rarefied Air, Electricity in various forms, Thermo-Cautery, Calisthenics, and Saratoga Waters, under the direction of a staff of educated physicians.

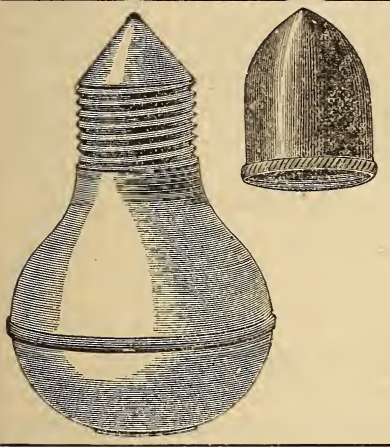
For Change: This Institution is located in a phenomenally dry, tonic, and quiet atmosphere, in the lower arc of the Adirondack Zone, and within the "Snow Belt."

For Rest: The Institution offers a well-regulated, quiet home, heated by steam and thoroughly ventilated, with cheering influences and avoiding the depressing atmosphere of invalidism.

For Recreation: To prevent introspection, are household sports at all seasons of the year, and in Winter, tobogganning, elegant sleighing etc.; in Summer, croquet, lawn-tennis, etc.

Private professional references furnished upon application. Physicians are invited to inspect the Institution at their convenience. A liberal discount to physicians and their families.

For further information, address, DRS. S. S. & S. E. STRONG.



THE P.P.P. SYRINGE

Is universally considered the most perfect urethral Syringe in the market, because it combines within itself all desirable qualities. It measures but 1½ x 2¾ inches, has a capacity of fully half an ounce, and is made of one piece of soft rubber with conical point. To protect this soft point and to prevent pocket dust from getting into the Syringe, a Hard Rubber cap screws air-tight over it and enables the patient to carry it in his pocket filled with the injection ordered, ready for use when away from home.

For sale by all druggists.

THE GOODYEAR RUBBER CO.,

49 MAIDEN LANE, NEW YORK.

A Phosphorized Cerebro-Spinant

(FRELIGH'S TONIC).

FORMULA.

Ten minims of the Tonic contain the equivalents (according to the formulæ of the U. S. P., and Dispensatory) of

Tinct. Nux Strychnos,	1	minim.
" Ignatia Amara,	1	"
" Cinchona,	4	"
" Matricaria,	1	"
" Gentian,	½	"
" Columbo,	½	"
" Phosphorus, C. P.,	1-300	gr.
Aromatics,	2	minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

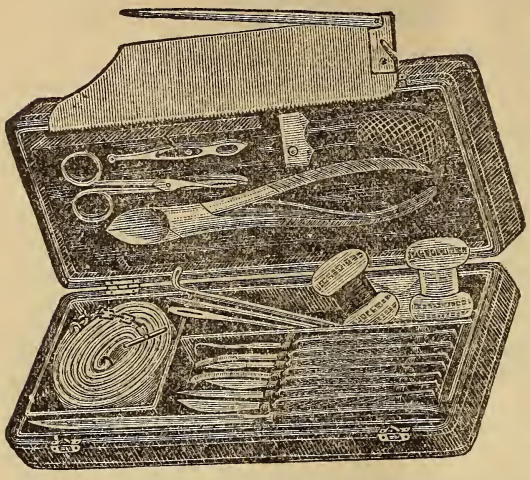
Manufacturers of Physicians' Specialties,

No. 88 Maiden Lane, New York City.

LENTZ'S ASEPTIC COMPACT OPERATING SET, No. 10.



We have from time to time made improvements to this set and are now making a perfect aseptic set, which offers especial facilities for aseptic precautions; the blades are soldered into hollow German-silver handles, nickel-plated, are light so as not to be unwieldy and admit of a firm grasp when operating.

The saw is adjusted to the handle on an entirely new principle, being made to separate easily and to facilitate thorough cleansing.

The handle is entirely of metal and fenestrated to overcome unnecessary weight.

Scissors and Forceps having French locks can be separated, and the slide can be easily removed from Artery and Needle Forceps.

Therefore, no opportunity is offered for the lodgment and development of germs.

The entire set is patterned with especial reference to facility in cleansing.

The instruments can be sterilized by placing them in boiling water, without fear of damaging them. Wood or rubber handles will not admit of this procedure. For price, see case A.

The following instruments are put up in either a fine Mahogany or Morocco case, with nickel trimmings, lined with velvet, and has an extra space for Trephine with handle, and Elevator if desired.

One Amputating Knife (6 in. blade); One Finger Knife; One Hernia Knife; One Sharp Curved Bistoury; Two Scalpels; One Tenotome; One Tenaculum; One Pair Scissors, curved or flat; One Saw (9 in. blade); One Liston's Bone Forceps, with Spring; One Artery and Needle Forceps, improved; One Esmarch's Flat Rubber Tourniquet, with Chain; One Hæmostatic Forceps; One Director, with Aneurism Needle; Two Silver Probes; Silk, Wire, Wax and Needles.

With the Sixteen Instruments Contained in this Case, any Ordinary Operation may be Performed.

SIZE, 11 INCHES LONG, 4 INCHES WIDE, 2 INCHES HIGH.

A.—German Silver aseptic Handles on Knives and Saw,	$34 00
B.—Hard Rubber aseptic Handles on Knives and Saw,	29 00
C.—Ebony Handles on Knives and Saw (as shown in illustration),	25 00
Either Set, with Trephine and Elevator in addition,	4 65

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the three Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the three Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

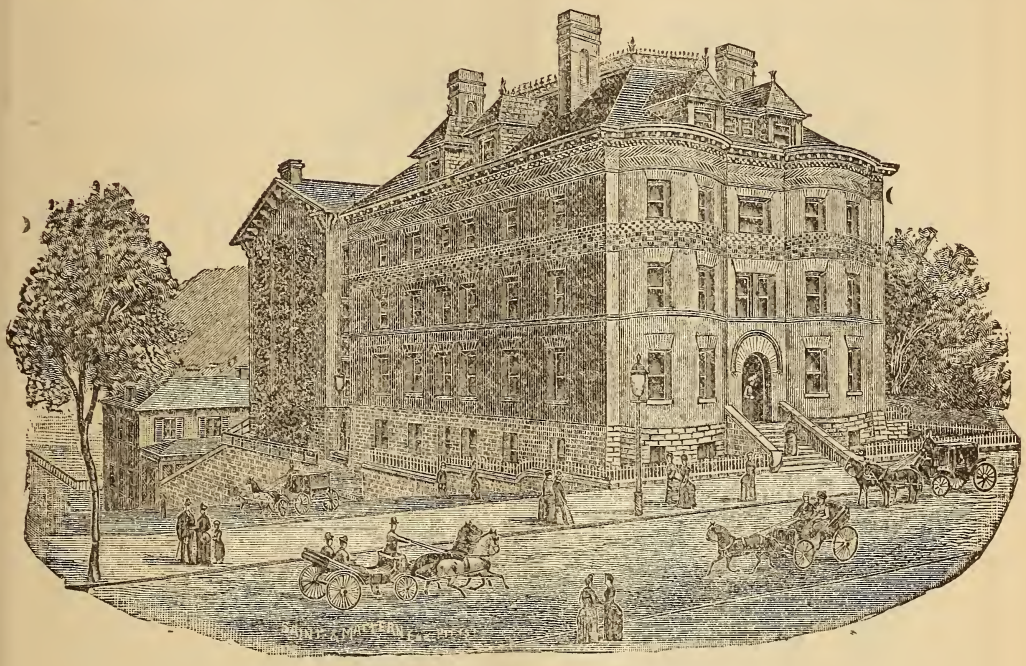
DR. R. S. SUTTON'S

Sanatorium for Diseases of Women.



Seventh Year Opens September 1, 1889.

ALLEGHENY CITY, PA.

This Institution is located on high ground, and overlooks the Allegheny, Monongahela and Ohio rivers; it commands a view of the city of Pittsburgh, and its picturesque surroundings. The building is large and beautiful, it is provided with every modern convenience, the halls are heated by steam, the rooms are commodious, well lighted and ventilated, and heated by open grates. The house is provided with a private parlor and reading-room for patients. The dining-room is large, handsomely finished, and furnished with small tables, securing privacy at meals for those who do not care to have meals served in their own rooms. Patients can be as secluded, should they desire it, as in a well appointed hotel. Each patient is examined by Dr. Sutton, and receives his daily personal attention, while Dr. J. H. Williamson, a physician of ample hospital experience, resides in the Institution, and has, under Dr. Sutton, the immediate care of the patients. The Institution accommodates 25 patients, and is equal in comfort to the best hotels.

Electricity, baths, douches, massage, local treatment, general medication and surgical operations are resorted to according to the requirements of each patient.

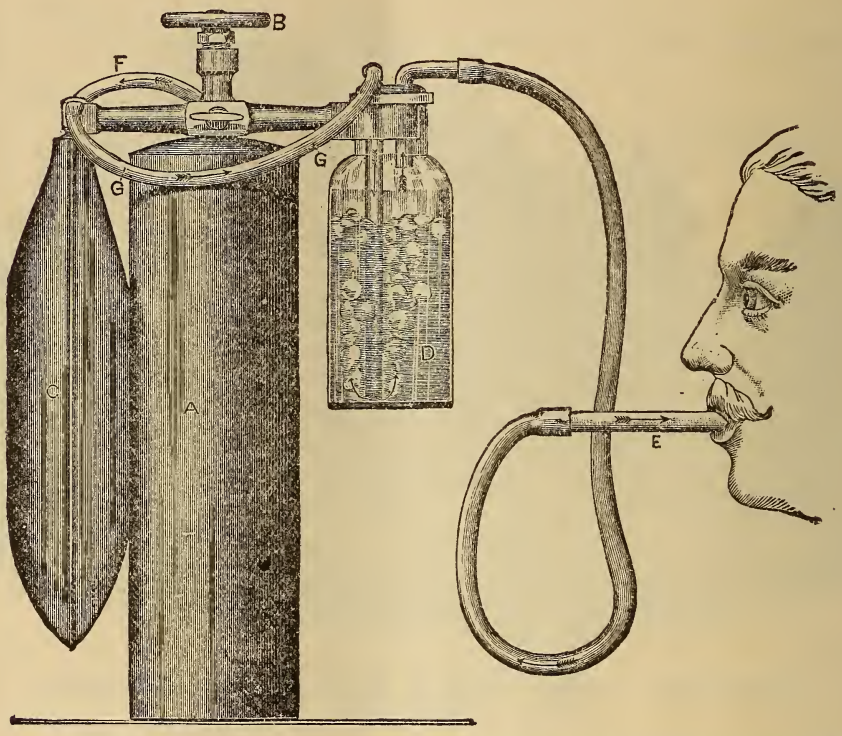
THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE S. S. WHITE DENTAL MFG. CO.,

PHILADELPHIA, NEW YORK, BOSTON, CHICAGO, BROOKLYN.

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request.

LAMBERT PHARMACAL CO., ST. LOUIS, MO.

FRENCH'S

COMPRESSED ANTISEPTIC PASTILLES.

(Dr. CARL SIELER'S FORMULÆ.)

FOR MAKING ANTISEPTIC SPRAYS, NASAL WASH, MOUTH WASH, Etc.

One tablet dissolved in four tablespoonfuls of warm water makes a solution which can be used as a spray or wash.

Supplied in bottles of 50, 100 and 1 lb.

COMPRESSED ANTISEPTIC TABLETS.

(FOR EXTERNAL USE.)

Each tablet contains:

7.3 grains . . . . . Hydrarg. Bichlor.
7.7 grains . . . . . Ammon. Clor.

One tablet dissolved in one pint of water will make a 1 to 1,000 solution, containing one part of Corrosive Sublimate in 1,000 parts of water.

Supplied in screw-cap bottles, containing 25 and 100 tablets each, and pounds.

FRENCH'S

COMPRESSED SULPHUR and CREAM OF TARTAR TABLETS.

An alterative and mild laxative for children and invalids. They are pleasantly flavored and sweetened, and form an agreeable method of medication.

FORMULA:

Sulphur Lotum, U. S. P. . . . . grs. v.
Potass. Bitart., pur. . . . . grs. xv in each tablet.

Put up in metal screw-cap glass jars, containing 35 tablets each. Also in 1 lb. bottles.

A sample of any of these preparations will be mailed to physicians free of charge, on application.

FOR SALE BY THE RETAIL DRUG TRADE GENERALLY.

FRENCH, RICHARDS & CO., Philadelphia, Pa.

Champagne ANALYZED

Of Interest to all Medical Practitioners.

WHAT IS SAID BY

THOMAS KING CHAMBERS, M.D., F.R.C.P.
R. OGDEN DOREMUS, M.D.
F. W. PAVY, M.D., F.R.S.

"Champagne, with a minimum of alcohol, is by far the wholesomest, and possesses remarkable exhilarating power."—THOMAS KING CHAMBERS, M.D., F.R.C.P.

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co.'s Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it not only for its purity but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M.D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

"Champagne, while only possessing the alcoholic strength of natural wines, is useful for exciting the flagging powers in case of exhaustion."—F. W. PAVY, M.D., F.R.S., *Lecturer on Physiology at Guy's Hospital, London.*

The remarkable vintage of 1884 of **G. H. MUMM & CO.'S EXTRA DRY CHAMPAGNE,** the finest for a number of years.
Pronounced by connoisseurs unsurpassed for excellence and bouquet.

FRED'K DE BARY & CO., New York,

SOLE AGENTS IN THE UNITED STATES AND CANADA.

REASONS FOR SPECIFYING FAIRCHILD'S PEPSIN.

It is the most active, gives the greatest value for the price asked.

One grain will digest more albumen than will a grain of any other pepsin made. We do not care by whose test, what the proportions of albumen, water, and acid, only let the conditions be the same for all.

It is positively guaranteed to be permanent. It will not get soft or sticky, or deteriorate in value, because it is not a peptone. It is free from all the well-known characteristics of peptone. It is not made by a patented or pirated process.

If you prescribe pepsin in scale or powder, and it becomes sticky, you may be sure that it is not Fairchild's. Investigate the matter, place the blame where it belongs.

There are pepsins "made to sell" under the title of scales—products which are inferior and dissimilar to Fairchild's pepsin in scales. They are peptones made by a patented process and sold under cover of a title first and properly used only by Fairchilds to describe their original, true pepsin in the form of scales.

The druggist is told "they are just as good as Fairchild's. If Fairchild's is not specified, put in mine." But claims and pretensions, however colossal, cannot make peptones permanent.

There is no soluble or peptone pepsin equal in activity to Fairchild's, none which will keep in all weathers and all conditions as Fairchild's will.

FAIRCHILD BROS. & FOSTER, NEW YORK.

"THIS IS AN AGE OF APOLLINARIS WATER."
—WALTER BESANT.

Apollinaris

"THE QUEEN OF TABLE WATERS."

The filling at the Apollinaris Spring (Rhenish Prussia), amounted to

11,894,000 BOTTLES IN **1887,**
12,720,000 BOTTLES IN **1888** AND
15,822,000 BOTTLES IN **1889.**

"The annual consumption of this favorite beverage affords a striking proof of the widespread demand which exists for table water of absolute purity, and it is satisfactory to find that, wherever one travels, in either hemisphere, it is to be met with; it is ubiquitous, and should be known as the cosmopolitan table water. 'Quod ab omnibus, quod ubique.'"—BRITISH MEDICAL JOURNAL.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2,50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

E. FOUGERA & CO., 30 North William St., New York.

Sole Agents for the above Preparations.

GARDNER'S

SYRUP OF HYDRIODIC ACID,

Introduced in 1878 by R. W. GARDNER.

The Reputation which Hydriodic Acid has Attained During the past Eleven Years was Won by this Preparation.

Numerous Imitations prepared differently, and weaker in Iodine, are offered, from the use of which the same therapeutic effects cannot be obtained.

Caution.—Use no Syrup of Hydriodic Acid which has turned red. This shows decomposition and free Iodine. In this state it acts as an irritant and fails to produce desirable results.

Unprincipled apothecaries substitute imitations when Gardner's Syrup is prescribed, and physicians, failing to get desirable and promised results, attribute the fault, unjustly, to Gardner's Syrup.

THERAPEUTIC INDICATIONS.

Hay Fever; Rose Cold; Poisoning by Lead, Mercury or Arsenic; Acute and Chronic Rheumatism; Asthma; Chronic Bronchitis; Catarrh; Congestion of Lungs in Children; Adenitis; Eczema; Lupus; Chronic Malarial Poisoning; Lumbago; Acute Pneumonia; Psoriasis; Scrofulous Diseases; Goitre; Enlarged Glands; Cold Abscesses; Indolent Sores; Excessive Fat; Fatty Degeneration of the Heart; to absorb non-malignant Tumors; and in the latter stages of Syphilis; Syphilitic Phthisis.

Details of treatment furnished physicians upon application to undersigned without charge.

Gardner's Chemically Pure Syrups of Hypophosphites.

Embracing the separate Syrups of Lime, of Soda, of Iron, of Potassa, of Manganese, and an Elixir of the Quinia Salt; enabling physicians to accurately follow Dr. Churchill's method, by which thousands of authenticated cases of Phthisis have been cured. The only salts, however, used by Churchill in Phthisis are those of Lime, of Soda, and of Quinia, and always separately according to indications,—never combined.

The reason for the use of single Salts is because of antagonistic action of the different bases, injurious and pathological action of Iron, Potassa, Manganese, etc., in this disease.

These facts have been demonstrated by thirty years' clinical experience in the treatment of this disease exclusively, by Dr. Churchill, who was the first to apply these remedies in Medical practice. Modified doses are also required in this disease; seven grains during twenty-four hours being the maximum dose in cases of Phthisis, because of increased susceptibility of the patient to their action, the danger of producing toxic symptoms (as hemorrhage, rapid softening of tubercular deposit, etc.), and the necessity that time be allowed the various functions to recuperate simultaneously; over-stimulation, by pushing the remedy, resulting in crisis and disaster.

A pamphlet of sixty-four pages, devoted to a full explanation of these details and others, such as contra-indicated remedies, indications for the use of each hypophosphite, reasons for the use of absolutely pure Salts, protected in Syrup from oxidation, etc., mailed to physicians without charge upon application to

R. W. GARDNER, 158 William St., N. Y. City.

W. H. SCHIEFFELIN & CO., Sole Wholesale Agents, New York.

CELERINA

NERVE TONIC, STIMULANT AND ANTISPASMODIC.

FORMULA.—Every Fluid Drachm represents FIVE grains EACH—Celery, Coca, Kola, Viburnum and Aromatics.

INDICATIONS.—Loss of Nerve-Power (so usual with Lawyers, Preachers, Writers and Business Men), Impotency, Spermatorrhea, Nervous Headache, Neuralgia, Paralysis, Hysteria, Opium Habit, Inebriety, Dyspepsia, and ALL LANGUID conditions of the System.

Indispensable to restore a patient after alcoholic excess.

DOSE.—One or two Teaspoonfuls three or more times a day, as directed by the Physician.

LIQUID IRON-RIO

Palatable and easily assimilated. Does not produce Nausea, nor irritate the Stomach. Does not Cause Headache, nor Constipate. Does not Stain the Teeth. It is so Acceptable to the Stomach that its Use is Admissible when all other forms of Iron would be rejected. Being so Readily Assimilable, it only requires a small Dose.

Each Fluid Drachm contains ONE GRAIN of Iron in a Pleasant and Digestible Form.

DOSE.—One or more Teaspoonfuls as indicated, during or after meals.

S. H. KENNEDY'S

CONCENTRATED EXTRACT OF

PINUS CANADENSIS

DARK. A NON-ALCOHOLIC LIQUID. WHITE.

A MOST VALUABLE NON-IRRITATING MUCOUS ASTRINGENT.

INDICATIONS.—Albuminuria, Diarrhea, Dysentery, Night-Sweats, Hemorrhages, Profuse Expectoration, Catarrh, Sore Throat, Leucorrhea, and other Vaginal Diseases, Piles, Sores, Ulcers, Burns, Scalds, Gonorrhea, Gleet, Etc.

When Used as an Injection, to Avoid Staining of Linen, the WHITE Pinus should be used.

RECOMMENDED BY PROMINENT EUROPEAN AND AMERICAN PHYSICIANS.

RIO CHEMICAL CO., St. Louis, Mo., U. S. A.

LONDON. PARIS. CALCUTTA. MONTREAL.

A CASE WITH A LESSON IN IT.

We have frequently referred to the necessity of keeping the pregnant woman supplied with those chemical substances which she must give to the child in the formation of its little frame, and the dire effects which may result from a deficiency of those substances. The headaches, neuralgias, spinal tenderness, and some of the many disorders of digestion, and even mental failure, may be all prevented or relieved by supplying to the mother the chemical food her system demands.

We have noticed a few cases where the most serious results have occurred to the mother by such a deficiency, one of which is well worth relating. Mrs. M., aged 30, pregnant with her third child, suffered from the second to the fifth month of her pregnant term with gradually failing strength and health, and nervous irritability. She was very restless nights for three or four days, the peculiar restlessness of complete nervous exhaustion, and was irrational for more than a week.

At this time I advised that she have a teaspoonful of Murdock's Liquid Food every hour in milk, and a little wine every four hours. The third night she had fifteen drops of hydrobromic acid dil. every three or four hours, which was continued for a week. The liquid food after a week every two hours, and all other medicines were discontinued. Her bowels were moved with a mild laxative at first, and afterward became regular. Her tongue cleaned quickly and her skin assumed a more natural appearance.

At this writing, less than three weeks from our first visit, the patient is able to sit up an hour at a time, is quite rational and cheerful, has a good appetite, the bowels are quite regular, there is no headache, and but little spinal tenderness. She sleeps reasonably well if fed frequently. She is allowed to suit her taste in her diet. The child is quite active, and the mother is progressing so nicely that it is hoped that she will pass safely through her confinement, which is nearly at hand. She will be kept on the liquid food and the phosphates until her confinement after which, the condition will suggest the treatment. This is the most marked case of a starved nervous system we have ever seen, and the benefit derived from the treatment proves the theory as to the cause of the trouble.

Apropos with the above, comes the question of the selection of nutritious foods for those many cases which demand strong and immediate nourishment. The food used in the above case has produced marvelous results for us in some of those extreme cases in which we have used it.

In one case of nervous exhaustion the insomnia was absolutely painful. When the exhaustion forced the patient to sleep there was an immediate sense of falling or approaching death, or there were hallucinations which were appalling, rendering the nights unbearable. One teaspoonful of Murdock's Liquid Food so nourished the system the first night it was given that the patient sank into a quiet, refreshing sleep which lasted, with a single awakening, until morning, and the improvement the patient obtained was most striking.

One case of mitral regurgitation with leucocythemia and nervous exhaustion improved more rapidly on this food than on all other measures combined. In cases of nervous exhaustion and brain tire, its effects are most marked, as we have experienced many times in the past five years in the frequent personal use of the agent. It contains the principles of pure, healthy blood and nerve tissue ready for immediate assimilation. Fourteen per cent. of the entire quantity is uncoagulated albumen, as we have demonstrated by actual analysis.

We have tided babies over critical periods often with a few drops in its usual diet. We have given it to dipsomaniacs with or without non-alcoholic stimulants with superb results. The sole objection our patients have to it is its odor. Its taste is not disagreeable; it has the odor and appearance of blood. All objections are soon forgotten, however, in the results of its action upon the nutrition of the system, and the patient soon learns to like it, and often craves for it, drinking it from the bottle or a glass readily, like any beverage. It ought to be the food par-excellence for rapid appropriation in all conditions of exhaustion.

P. S.—Phosphates act well with the Liquid Food.

Editorial of the Chicago *Medical Times*, June, 1890.

In 97% of all cases where mother's milk is scanty or poor a copious flow of rich milk will be caused in 3 days by giving the mother "nutrolactis". Using this remedy mothers become stronger, infants thrive notably. Try it Doctor

For circulars, address

A. F. A. KING, M. D., DEAN, 726 THIRTEENTH ST., N. W., WASHINGTON D. C.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 125TH ANNUAL WINTER SESSION will begin Wednesday, October 1st, 1890, at 12 M., and will continue seven months. The PRELIMINARY SESSION begins September 22d, 1890, the Spring Term early in May, 1891.

The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D., LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.
JAMES TYSON, M.D., Professor of Clinical Medicine.
HORATIO C. WOOD, M.D., LL.D., Professor of Materia Medica, Pharmacy and General Therapeutics.
THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry and Toxicology.
JOHN ASHHURST, JR., M.D., Professor of Surgery and of Clinical Surgery.
EDWARD T. REICHERT, M.D., Professor of Physiology.
WILLIAM F. NORRIS, M.D., Honorary Prof. of Ophthalmology
BARTON COOKE HIRST, M.D., Professor of Obstetrics.
J. WILLIAM WHITE, M.D., Professor of Clinical Surgery.
JOHN GUITÉRAS, M.D., Professor of General Pathology and Morbid Anatomy.
GEORGE A. PIERSOL, M.D., Professor of Histology and Embryology.
SAMUEL G. DIXON, M.D., Professor of Hygiene.

For Catalogue and announcement containing particulars, apply to

DR. JAMES TYSON, Dean,
36th and Woodland Avenue, Philadelphia.

Requires No Cooking.

Liebig demonstrated that the best substitute for normal human milk was not the milk of any animal, but a combination of animal milk with the elements of those grains which are used in repairing waste, building tissues, and generating heat.

Mellin's Food

Dissolved in hot water and milk, according to the directions, is the genuine Liebig's Food, and promotes in infants a healthy growth, a full development, and a vigorous constitution. *It requires no cooking.*

DOLIBER-GOODALE CO., BOSTON, MASS.

College of Physicians and Surgeons

OF CHICAGO.

One of the Largest, Finest, and Best Arranged College Buildings in this country. Heated by Steam throughout, and perfectly lighted and ventilated.

Clinical Advantages Unsurpassed.

PROFESSORS.—A. Reeves Jackson, S. A. McWilliams, D. A. K. Steele, L. St. John, Henry Palmer, F. E. Waxham, J. E. Harper, A. W. Harlan, A. E. Hoadley, C. C. P. Silva, O. A. King, R. J. Curtis, W. E. Quine, W. K. Harrison, J. T. Jelks, H. J. Reynolds, Christian Fenger, Chas. B. Gibson, J. A. Benson, H. P. Newman, C. Rutherford, R. W. Jones Caldwell.

REGULAR SESSION opens September 23.

FEES.—Matriculation $5 00; General Ticket, admitting to all the Lectures, and including all Practical Work in Histological and Physiological Laboratories, $60.

For further information, address

STUDENTS' MICROSCOPES $38.00 TO $46.00 COMPLETE.

ILLUSTRATED CATALOGUE ON APPLICATION.

The only prominent Emulsion of Cod-Liver Oil introduced directly to the medical profession. It is advertised exclusively in medical journals.

HYDROLEINE.

(HYDRATED OIL.)

Produces rapid increase in Flesh and Strength.

FORMULA.—Each Dose contains:

Pure Cod Liver Oil	30 m. (drops)	Soda	1-3 Grains.
Distilled Water	35 "	Salicylic Acid	1-4 "
Soluble Pancreatin	5 Grains.	Hyochoic Acid	1-30 "

Recommended and Prescribed by EMINENT PHYSICIANS Everywhere. It is pleasant to the Taste and acceptable to the most delicate Stomach.

IT IS ECONOMICAL IN USE AND CERTAIN IN RESULTS.

HYDROLEINE (Hydrated Oil) is not a simple alkaline emulsion of oleum morrhuæ, but a hydro-pancreated preparation, containing acids and a small percentage of soda. Pancreatin is the digestive principle of fatty foods, and in the soluble form here used, readily converts the oleaginous material into assimilable matter, a change so necessary to the reparative process in all wasting diseases.

The following are some of the diseases in which HYDROLEINE is indicated:

Phthisis. Tuberculosis, Catarrh, Cough, Scrofula, Chlorosis, General Debility, etc.

TO BRAIN WORKERS of all classes, **HYDROLEINE** is invaluable,—supplying as it does, the true brain-food, and being more easily assimilated by the digestive organs than any other emulsion.

The principles upon which this discovery is based have been described in a treatise on "The Digestion and Assimilation of Fats in the Human Body," and "Consumption and Wasting Diseases," by two distinguished London physicians, which will be sent free on application.

SOLD BY DRUGGISTS GENERALLY.

C. N. CRITTENTON,

SOLE AGENT FOR THE UNITED STATES. 115 FULTON STREET, N. Y.

A Sample of Hydroleine will be sent free upon application, to any physician (enclosing business card) in the U. S.

INDIGESTION

"and acidity of the stomach will in a large majority of cases be counteracted by a systematic use of good sound Burgundy. I know of none better than the Royal Burgundy (Calvico brand only)."

An Open Letter to the Medical Profession.

THE INFANT FOOD PROBLEM SOLVED.

NEW YORK, May 1, 1890.

The Annual of the Universal Medical Sciences for 1889 says: "A perfect Infant Food is still a desideratum; such a food will probably be evolved in the mind of some manufacturer who understands the physiology of infantile digestion and the chemistry of milk. A substitute for human milk to approximate the latter closely should be made entirely from cow's milk, without the addition of any ingredient not derived from milk."

"But not alone do we demand that these Milk Foods contain the equivalent of the solids in human milk, and especially of the albuminoids derived from milk, but that the latter be gathered with the utmost care from properly fed animals, transported with the least possible jolting to the factory, maintained during its transit at a low temperature, then transferred to an apparatus for sterilization, and immediately after the latter has been accomplished reduced to the dry state, in order to prevent the formation of those organisms which Loeffer, Pasteur, and Lester have found to develop in fluid milk after boiling under an alkaline reaction. If such a preparation be put into air-tight and sterilized jars, all will have been accomplished that can be done to render the food sterile, and thus fulfil the chief indications in the prevention of the most serious gastro-intestinal derangements."

"Such a food, too, would have the advantage of being easily and rapidly prepared by addition of sterilized water, affording an altogether sterilized food."

To the *Medical Profession* at large we submit for examination and trial the perfected Milk Food known as LACTO-PREPARATA. We claim that LACTO-PREPARATA is an *ideal Infant Food*, and that it fulfils the above requirements in every particular, except the partial substitution of cocoa-butter for unstable milk-fat. This substitution was made by advice of Prof. Attfield, London, who made extensive tests of its food value and digestibility in the London Hospitals for Infants.

LACTO-PREPARATA is made from cow's milk evaporated in vacuo a few hours after it leaves the udder. In order to have the product correspond in composition with breast-milk, sufficient milk-sugar is added to bring up the carbohydrates and reduce the albuminoids to a proper proportion (17 per cent.). The casein is partially pre-digested (30 per cent.), and the remaining portion is rendered like human milk in character and digestibility. The ingredients are perfectly sterilized and placed in hermetically sealed cans; the powdering, bolting, and canning are done in an air-tight room, all air entering and leaving this room is forced by a blower through heavy layers of cotton. LACTO-PREPARATA is adapted more especially to infants from birth to six months of age; *and by the addition of water alone represents almost perfectly human milk in taste, composition, and digestibility.*

Another product of our laboratory which has been before the profession for a number of years is CARNRICK'S SOLUBLE FOOD, which, as now prepared and perfected, contains 37½ per cent. of the solid constituents of milk, 37½ per cent. of wheat with the starch converted into dextrine and soluble starch, and 25 per cent. additional milk-sugar. For infants over six months of age it is perfect in every respect; for infants younger than this, LACTO-PREPARATA is more suitable, although *Soluble Food* has also been used largely from birth with the most satisfactory results.

Samples will be sent prepaid, also pamphlet giving detailed description.

REED & CARNRICK, NEW YORK.

TO THE MEDICAL PROFESSION.

SPECIAL MENTION.

In offering these special preparations, there is no attempt made to "prescribe for the physician," but simply to place within his reach elegant and palatable combinations of known value, such as local pharmacists ordinarily have not the means of preparing.

Among our leading specialties we take pleasure in mentioning the following:

ALKALINE ELIXIR RHUBARB CO. AND PANCREATIN.

A combination of E. I. Rhubarb and Potass. Bicarbonate, āā 20 grs., Pancreatin, 16 grs., and Fluid Hydrastis, 10 ♏ to the fluid ounce. This is unequalled as an antacid, carminative, stomachic and digestive. It is very valuable in cholera infantum, infantile colics, dyspepsia and all abnormally acid conditions of the alimentary tract. Dose ½ to 4 teaspoonfuls every 1 to 4 hours, according to case and age.

ESSENCE OF PEPSIN (FLUID PEPSIN).

A direct solution of all the soluble constituents of the peptic glands of the pig's stomach, unchanged by chemical action or manipulation.

It is without bad odor or taste, and represents, in each fluid drachm, the digestive power of at least 20 grs. U. S. P. Sacch. Pepsin.

Readily used as a basis to which may be added Ammonio Cit. Bismuth, Strychnia, etc., as indicated.

This preparation is rapidly assuming its proper position *at the very front* of all preparations of pepsin.

NUTRITIVE HYPOPHOSPHITES.

A combination of the well-known formula of the hypophosphites of Lime, Soda, Iron, Potass., Quin., Strychnine and Manganese, with a vehicle of glycerine and cane-sugar syrup instead of glucose. More palatable, more permanent, and less likely to disturb the stomach. It is sold as a legitimate pharmaceutical preparation at legitimate prices, and is unequalled in elegance and efficacy by any similar preparation.

Specify Nutritive Hypophos.: Merrell.

ELIXIR PINUS COMPOSITUS.

Considered by those who have used it as the most valuable routine expectorant in the market. It is unlike the many syrups, etc., under similar names, and the difference will be readily appreciated when tried. Formula supplied to the profession.

EXTRACT TRIFOLIUM COMPOUND.

From the well-known and approved prescription of Dr. E. F. Rush, prepared in a concentrated form, one bottle will make 3 pints Syr. Trifolium comp'd. By its use a stronger or weaker syrup may be prepared as indicated. Formula furnished.

"Merrell Co.'s" "Green Drug," Fluid Extracts, True Salicylic Acid, Salts of Hydrastis, Fluid Hydrastis and Specialties may be obtained of wholesale druggists throughout the United States, at the Home Office at Cincinnati, or the New York Office, 96 Maiden Lane, New York City, Smith, Kline & Co., Philadelphia. Prices current and printed matter cheerfully supplied.

PIL. PHENACETINE ET SALOL, 5 GRS., "W. H. S. & CO."

{Phenacetine-Bayer, ... 2½ grs.}
{Salol, ... 2½ grs.}

Anti-Rheumatic and Analgesic. This combination was first suggested by Dr. M. F. Price, Colton, Cal., President of the "Southern California Medical Society." In an address to the members he says: "In a case of acute Rheumatism, affecting elbows, wrists, knees, and ankles, ordered Phanacetine and Salol every three hours. No local application ordered. Made five daily visits, found the patient each day improved, discharged with orders to continue the medicine three times a day for a week."

After citing other cases, one of Sciatica where the patient was suffering such pain that the slightest motion caused faintness with nausea and continuous vomiting; two with acute Rheumatism, and one with Neuralgia of the stomach, Dr. Price continues:

"It will be observed that in some of these cases I have combined Salol with Phanacetine. I did this on the principle of the well-known effect of Salicylic Acid in Rheumatism, but I rely on the Phenacetine for the relief of the pain, and in this way perhaps the cure of the disease causing it." (*Southern California Practitioner*, August, 1889.)

PIL. TERPIN HYDRAT., 2 GRS., "W. H. S. & CO.,"

A new and potent remedy in the treatment of coughs, catarrh, bronchitis, and kindred diseases.

Terpin Hydrate is indicated in cases where violent irritation of the bronchial mucous membrane exists, and where the secretion is inconsiderable and peculiarly viscid, such as is met with in the chronic catarrh accompanying emphysema and phthisis. The effect obtained is always an increase and a liquefaction of the secretion, a considerable reduction of the irritation, and easy expectoration.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced in their present excellent quality.

The conditions of a perfect Pill are:

1*st.* *Ingredients of the finest quality.*
2*d.* *All materials weighed with scrupulous exactness.*
3*d.* *The mass sufficiently consistent to maintain the globular form, and yet readily soluble in the stomach.*
4*th.* *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

The continued favor which has been shown to our **Soluble Pills** is sufficient evidence that care has been bestowed upon their manufacture.

As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and they invite the most critical examination and test, either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque, nor insuluble, but elastic, thin, transparent, and readily soluble.

For further information about them we refer to our formula books and price lists, which we shall be happy to furnish upon application.

THE P.P.P. SYRINGE

Is universally considered the most perfect urethral Syringe in the market, because it combines within itself all desirable qualities. It measures but 1½ x 2¾ inches, has a capacity of fully half an ounce, and is made of one piece of soft rubber with conical point. To protect this soft point and to prevent pocket dust from getting into the Syringe, a Hard Rubber cap screws air-tight over it and enables the patient to carry it in his pocket filled with the injection ordered, ready for use when away from home.

For sale by all druggists.

THE GOODYEAR RUBBER CO.,

49 MAIDEN LANE, NEW YORK.

A Phosphorized Cerebro-Spinant

(FRELIGH'S TONIC).

FORMULA.

Ten minims of the Tonic contain the equivalents (according to the formulæ of the U. S. P., and Dispensatory) of

Tinct. Nux Strychnos,	1	minim.
" Ignatia Amara,	1	"
" Cinchona,	4	"
" Matricaria,	1	"
" Gentian,	½	"
" Columbo,	½	"
" Phosphorus, C. P.,	1-300	gr.
Aromatics,	2	minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

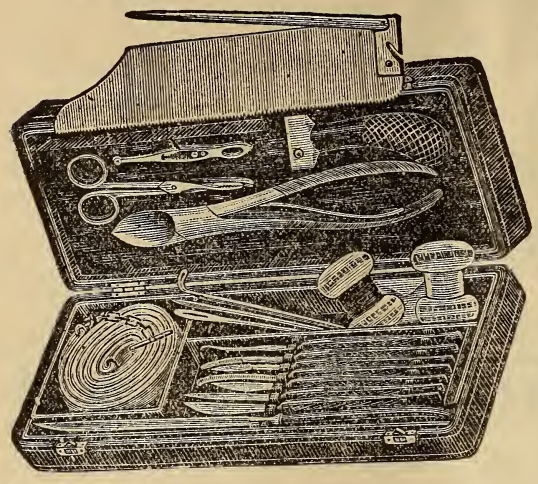
Manufacturers of Physicians' Specialties,

No. 88 Maiden Lane, New York City.

LENTZ'S ASEPTIC COMPACT OPERATING SET, No. 10.



We have from time to time made improvements to this set and are now making a perfect aseptic set, which offers especial facilities for aseptic precautions; the blades are soldered into hollow German-silver handles, nickel-plated, are light so as not to be unwieldy and admit of a firm grasp when operating.

The saw is adjusted to the handle on an entirely new principle, being made to separate easily and to facilitate thorough cleansing.

The handle is entirely of metal and fenestrated to overcome unnecessary weight.

Scissors and Forceps having French locks can be separated, and the slide can be easily removed from Artery and Needle Forceps.

Therefore, no opportunity is offered for the lodgment and development of germs.

The entire set is patterned with especial reference to facility in cleansing.

The instruments can be sterilized by placing them in boiling water, without fear of damaging them. Wood or rubber handles will not admit of this procedure. For price, see case A.

The following instruments are put up in either a fine Mahogany or Morocco case, with nickel trimmings, lined with velvet, and has an extra space for Trephine with handle, and Elevator if desired.

One Amputating Knife (6 in. blade); One Finger Knife; One Hernia Knife; One Sharp Curved Bistoury; Two Scalpels; One Tenotome; One Tenaculum; One Pair Scissors, curved or flat; One Saw (9 in. blade); One Liston's Bone Forceps, with Spring; One Artery and Needle Forceps, improved; One Esmarch's Flat Rubber Tourniquet, with Chain; One Hæmostatic Forceps; One Director, with Aneurism Needle; Two Silver Probes; Silk, Wire, Wax and Needles.

With the Sixteen Instruments Contained in this Case, any Ordinary Operation may be Performed.

SIZE, 11 INCHES LONG, 4 INCHES WIDE, 2 INCHES HIGH.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the three Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the three Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

OTTO FLEMMING,

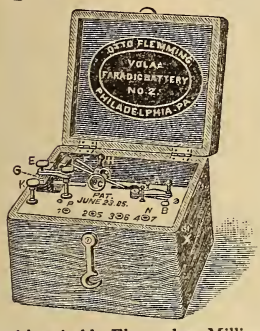
MANUFACTURER OF

Electric Specialties,

FOR USE IN

MEDICINE and SURGERY.

1009 Arch St., Phila., Pa.



I invite the closest scrutiny, analysis, and tests of the qualities of my new Vola-Batteries; my claim being, superior efficiency and regularity in their working capacity by perfect absence of annoyance, resulting from fluid in the cells. Complete apparatus for use in Electro-Gynæcology, with suitable Electrodes, Milliampere Meters, Current Controllers, Cautery Batteries, etc.

DR. MASSEY'S PRIVATE SANITARIUM

3607 Locust Street

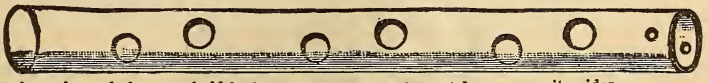
PHILADELPHIA

This institution, in addition to complete arrangements for the treatment of Nervous Diseases by rest, electricity, massage, etc., under comfortable surroundings, is specially equipped for the treatment of cases of Fibroid Tumors and other intractable diseases of the pelvic viscera, by the conservative use of strong electric currents. For particulars, address

DR. G. BETTON MASSEY

1706 Walnut Street, Philadelphia

ANTISEPTIC DRAINAGE TUBES.—Glass.



These Tubes have large holes, one-half inch apart, arranged alternately on opposite sides.
They are carefully finished, especial care being taken to make them smooth.
In addition to the drainage-holes, each tube has at one end two smaller holes for the insertion of a Safety-Pin, through which it is prevented slipping into the wound.

FURNISHED IN SEVEN SIZES.

No. 1,	$1.25 per doz.	No. 4,	$1.55 per doz.
No. 2,	1.25 "	No. 5,	1.70 "
No. 3,	1.40 "	No. 6,	1.90 "

No. 7, $2.10 per dozen.

RAW CAT-GUT. I put this up in coils of 10 feet, four different sizes, Nos. 1, 2, 3, 4 (4 is thickest). Nos. 2 and 3 are the most useful sizes. **No. 1 Coil, 10 Cents; No. 2 Coil, 12 Cents; No. 3 Coil, 14 Cents; No. 4 Coil, 16 Cents.** Full directions with each coil for making it absolutely aseptic.

ONEITA

The perfection of table waters, with mineral properties unsurpassed in the treatment of Dyspepsia, Kidney and Liver troubles, Gout, Rheumatism, etc. The analysis of the spring shows a combination of mineral virtues unequaled in any other water. The water has been before the public but a short time, yet in that time has won public favor to a marked degree. Send for analysis of C. F. Chandler, Ph. D.

ONEITA SPRING CO.,

UTICA, N. Y.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

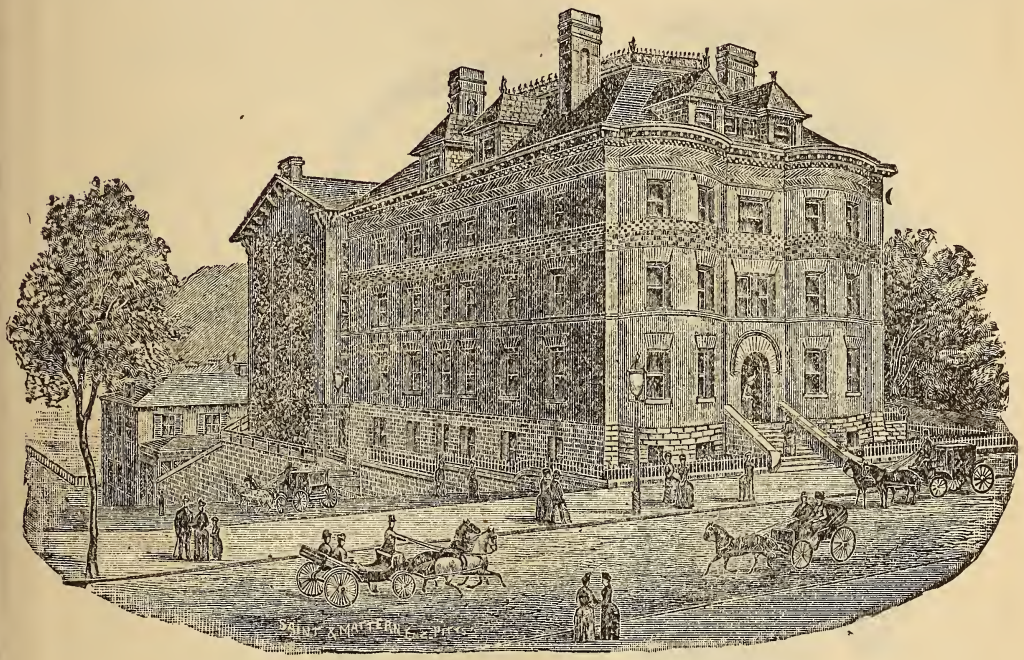
DR. R. S. SUTTON'S

Sanatorium for Diseases of Women.



Eighth Year Opens September 1, 1890.

ALLEGHENY CITY, PA.

This Institution is located on high ground, and overlooks the Allegheny, Monongahela and Ohio rivers; it commands a view of the city of Pittsburgh, and its picturesque surroundings. The building is large and beautiful, it is provided with every modern convenience, the halls are heated by steam, the rooms are commodious, well lighted and ventilated, and heated by open grates. The house is provided with a private parlor and reading-room for patients. The dining-room is large, handsomely finished, and furnished with small tables, securing privacy at meals for those who do not care to have meals served in their own rooms. Patients can be as secluded, should they desire it, as in a well appointed hotel. Each patient is examined by Dr. Sutton, and receives his daily personal attention, while Dr. J. H. Williamson, a physician of ample hospital experience, resides in the Institution, and has, under Dr. Sutton, the immediate care of the patients. The Institution accommodates 25 patients, and is equal in comfort to the best hotels.

Electricity, baths, douches, massage, local treatment, general medication and surgical operations are resorted to according to the requirements of each patient.

For further information address the Matron

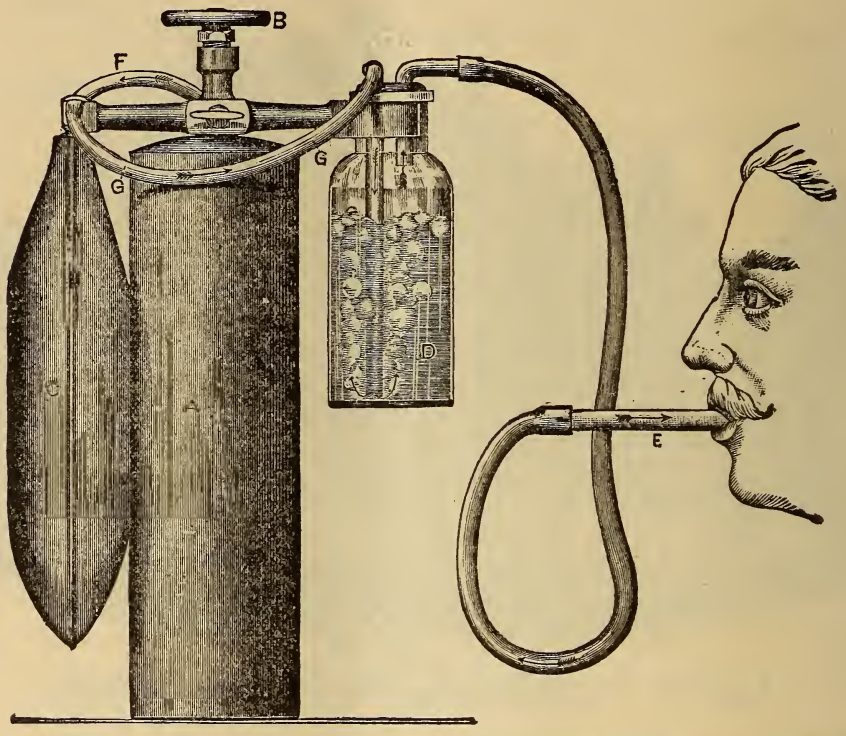
MISS KENNEDY,

170 Ridge Ave., Allegheny, Pa.

INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request:

SPECIAL and RELIABLE FORMULÆ for PHYSICIANS' PRESCRIBING

The Coating will Dissolve in 4½ Minutes.

PIL. SUMBUL COMP.
(Wm. R. Warner & Co.)

(DR. GOODELL.)

℞—Ext. Sumbul .....1 gr. | Ferri Sulph. Ext.....1 gr.
Assafœtida ..... 2 gr. | Ac. Arsenious .....1-30 gr.

"I use this pill for nervous and hysterical women who need building up." This pill is used with advantage in neurasthenic conditions in connection with Warner & Co.'s Bromo-Soda, one or two pills taken three times a day.

PIL. LADY WEBSTER.
(Wm. R. Warner & Co.)

℞ Pulv. Aloes.....2 gr. | Pulv. Rose los.....½ gr.
" Mastic . ... ½ gr. | M. ft. one pill.

Lady Webster Dinner Pills. This is an excellent combination officially designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when given in doses of one pill after dinner.

PIL. ALOIN, BELLADONNA, AND STRYCHNINE.
(Wm. R. Warner & Co.)

℞—Aloin, 1-5 gr. Strychnine, 1-60 gr. Ext. Belladonna, ⅓ gr.

Medical Properties—Tonic, Laxative. Dose, 1 to 2 Pills.

Try this Pill in habitual constipation.

PIL. ARTHROSIA.
(Wm. R. Warner & Co.)

FOR CURE OF RHEUMATISM AND RHEUMATIC GOUT.

Formula.—Acidum Salicylicum; Resina Podophyllum; Quinia; Ext. Colchicum; Ext. Phytolacca; Capsicum.

Almost a specific in Rheumatic and Gouty Affections.

PIL. CHALYBEATE COMP.
(Wm. R. Warner & Co.)

Same as Pil. Chalybeate, with 1-6 gr. Ext. Nux Vomica added to each Pill to increase the tonic effect. Dose, 1 to 3 Pills.

PIL. DIGESTIVA.
(Wm. R. Warner & Co.)

A VALUABLE AID TO DIGESTION.

℞—Pepsin Conc't.....1 gr. | Gingerine.....1-16 gr.
Pv. Nux Vom..... ¼ gr. | Sulphur.....⅛ gr.

IN EACH PILL.

This combination is very useful in relieving various forms of Dyspepsia and Indigestion, and will afford permanent benefit in cases of enfeebled digestion, where the gastric juices are not properly secreted.

As a dinner pill, Pil. Digestiva is unequalled, and may be taken in doses of a single pill either before or after eating.

J. B. LIPPINCOTT COMPANY

HAVE JUST PUBLISHED

A Text-Book of Clinical Diagnosis.

The Chemical, Microscopical, and Bacteriological Evidence of Disease. By DR. RUDOLPH VON JAKSCH, of the University of Prague. Translated from the *second edition* by JAMES CAGNEY, M. A., M. D. With additions by WM. STIRLING, M. D., Sc. D., Professor of Physiology, Owens College, Manchester. With numerous illustrations in color. Medium 8vo. Cloth, $6.50.

"Dr. Jaksch's work on Clinical Diagnosis will be welcomed by students in this country, now that it has become accessible to the English-speaking students by Dr. Cagney's able translation. The book is thoroughly original and well up to date. The book is one that has earned great reputation in Germany, and the English edition contains additions and explanations by the translator and supplemented by a valuable appendix by Dr. William Stirling, the translator of Landois' well-known work on physiology. The book abounds in excellent illustrations, many of which are colored. Special attention is given to the bacteriology of the blood, sputum, and feces, and a chapter is devoted to the methods of bacteriological research."—*Medical and Surgical Reporter, Philadelphia.*

"THIS IS AN AGE OF APOLLINARIS WATER."
—WALTER BESANT.

Apollinaris

"THE QUEEN OF TABLE WATERS."

The filling at the Apollinaris Spring (Rhenish Prussia), amounted to

11,894,000 BOTTLES IN **1887,**
12,720,000 BOTTLES IN **1888** AND
15,822,000 BOTTLES IN **1889.**

"The annual consumption of this favorite beverage affords a striking proof of the widespread demand which exists for table water of absolute purity, and it is satisfactory to find that, wherever one travels, in either hemisphere, it is to be met with; it is ubiquitous, and should be known as the cosmopolitan table water. 'Quod ab omnibus, quod ubique.'"—BRITISH MEDICAL JOURNAL.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

REASONS FOR SPECIFYING FAIRCHILD'S PEPSIN.

It is the most active, gives the greatest value for the price asked.

One grain will digest more albumen than will a grain of any other pepsin made. We do not care by whose test, what the proportions of albumen, water, and acid, only let the conditions be the same for all.

It is positively guaranteed to be permanent. It will not get soft or sticky, or deteriorate in value, because it is not a peptone. It is free from all the well-known characteristics of peptone. It is not made by a patented or pirated process.

If you prescribe pepsin in scale or powder, and it becomes sticky, you may be sure that it is not Fairchild's. Investigate the matter, place the blame where it belongs.

There are pepsins "made to sell" under the title of scales—products which are inferior and dissimilar to Fairchild's pepsin in scales. They are peptones made by a patented process and sold under cover of a title first and properly used only by Fairchilds to describe their original, true pepsin in the form of scales.

The druggist is told "they are just as good as Fairchild's. If Fairchild's is not specified, put in mine." But claims and pretensions, however colossal, cannot make peptones permanent.

There is no soluble or peptone pepsin equal in activity to Fairchild's, none which will keep in all weathers and all conditions as Fairchild's will.

FAIRCHILD BROS. & FOSTER, NEW YORK.

ALETRIS CORDIAL

UTERINE TONIC AND RESTORATIVE.

Prepared from the Aletris Farinosa or True Unicorn and Aromatics.

INDICATIONS.

Amenorrhea, Dysmenorrhea, Leucorrhea, Prolapsus Uteri, Sterility, to Prevent Miscarriage, Etc.

DOSE:—ONE TEASPOONFUL THREE OR FOUR TIMES A DAY.

UNRIVALED AS A UTERINE TONIC IN IRREGULAR, PAINFUL, SUPPRESSED AND EXCESSIVE MENSTRUATION.

It Restores Normal Action to the Uterus, and Imparts Vigor to the Entire Uterine System.

☞Where women have miscarried during previous pregnancies, or in any case where miscarriage is feared, the ALETRIS CORDIAL is indicated, and should be continuously administered during entire gestation.

CHAS. CLAY, M. R. C. S., Manor House, Dewsbury, England, says:—I find Aletris Cordial (Rio) is of great service in threatened miscarriage.

FRANCIS E. CANE, L. R. C. S., &c., Leeds, England, says:—I have tried the Aletris Cordial (Rio) in two cases of long standing dysmenorrhea, with excellent results. One of these patients has spent a week in bed every month for two years. After all the usual remedies, I put her on Aletris Cordial, and for the last two periods she has been out and about all the time.

L. M. WATSON, M. D., Delhi, Ills., says:—I have used Aletris Cordial (Rio) in cases of dysmenorrhea. suppressed menses and threatened miscarriage, and also, combined with Celerina, as a tonic after confinement, with the happiest results, and now I am using it on a case of leucorrhea, with injections of S. H. Kennedy's Extract of Pinus Canadensis, and it is acting like a charm.

P. H. OWEN, M. D., Morganville, Ala., says:—I have prescribed Aletris Cordial (Rio) in several cases with the most satisfactory results, and regard it as the best uterine tonic I have met with in a professional experience of over twenty-five years. In cases of threatened miscarriage it acts like a charm. Would recommend its continuous administration in all cases when there is any indication of miscarriage.

Dr. W. BERTHELOT, Santander, Spain, says:—I have tried the Aletris Cordial (Rio), and it has seemed to me to be useful, especially in cases of dysmenorrhea.

Dr. RASQUINET, Jupile, near Liege, Belgium, says:—I tried Aletris Cordial (Rio) in the case of a woman who had had several miscarriages at the end of five months, and who is now again pregnant, having reached the seventh month. thanks to Aletris Cordial.

R. REECE, M. R. C. S., Walton-on-Thames, England, says:—Aletris Cordial (Rio) in painful menstruation is most valuable. A wife of a minister suffered much, and had had three miscarriages. I prescribed Aletris Cordial. She has for the first time, gone her full time, and was safely confined with a male child.

J. T. COLLIER, M. D., Brooks, Me., says:—I have used your Aletris Cordial (Rio) in cases of females at the menopause. Consider it one of the finest remedies for these cases.

Dr. GORDILLON, St. Amand, France, says: I have tried the Aletris Cordial (Rio) in a case of dysmenorrhea. The result I obtained from the use of your preparation was excellent, better than I had obtained in the same patient by prescribing the usual remedies employed in such cases.

W. F. TOOMBS, M. D., Morrillton, Ark., says:—I have used a great deal of your Aletris Cordial (Rio) and I find it all you claim for it in amenorrhea, dysmenorrhea, metritis, leucorrhea; I don't think it has an equal. I have used it in two cases of threatened miscarriage and the trouble was obviated. For a general Uterine Tonic I know of nothing superior.

R. D. PATTERSON, L. R. C. S. &c., Medical Officer, Caledon Dispensary, Co. Tyrone, Ireland, says:—I have very great pleasure in testifying to the very high opinion I hold of Aletris Cordial (Rio) in threatened miscarriage.

RIO CHEMICAL CO., ST. LOUIS, MO., U. S. A.

A CASE WITH A LESSON IN IT.

We have frequently referred to the necessity of keeping the pregnant woman supplied with those chemical substances which she must give to the child in the formation of its little frame, and the dire effects which may result from a deficiency of those substances. The headaches, neuralgias, spinal tenderness, and some of the many disorders of digestion, and even mental failure, may be all prevented or relieved by supplying to the mother the chemical food her system demands.

We have noticed a few cases where the most serious results have occurred to the mother by such a deficiency, one of which is well worth relating. Mrs. M., aged 30, pregnant with her third child, suffered from the second to the fifth month of her pregnant term with gradually failing strength and health, and nervous irritability. She was very restless nights for three or four days, the peculiar restlessness of complete nervous exhaustion, and was irrational for more than a week.

At this time I advised that she have a teaspoonful of Murdock's Liquid Food every hour in milk, and a little wine every four hours. The third night she had fifteen drops of hydrobromic acid dil. every three or four hours, which was continued for a week. The liquid food after a week every two hours, and all other medicines were discontinued. Her bowels were moved with a mild laxative at first, and afterward became regular. Her tongue cleaned quickly and her skin assumed a more natural appearance.

At this writing, less than three weeks from our first visit, the patient is able to sit up an hour at a time, is quite rational and cheerful, has a good appetite, the bowels are quite regular, there is no headache, and but little spinal tenderness. She sleeps reasonably well if fed frequently. She is allowed to suit her taste in her diet. The child is quite active, and the mother is progressing so nicely that it is hoped that she will pass safely through her confinement, which is nearly at hand. She will be kept on the liquid food and the phosphates until her confinement after which, the condition will suggest the treatment. This is the most marked case of a starved nervous system we have ever seen, and the benefit derived from the treatment proves the theory as to the cause of the trouble.

Apropos with the above, comes the question of the selection of nutritious foods for those many cases which demand strong and immediate nourishment. The food used in the above case has produced marvelous results for us in some of those extreme cases in which we have used it.

In one case of nervous exhaustion the insomnia was absolutely painful. When the exhaustion forced the patient to sleep there was an immediate sense of falling or approaching death, or there were hallucinations which were appalling, rendering the nights unbearable. One teaspoonful of Murdock's Liquid Food so nourished the system the first night it was given that the patient sank into a quiet, refreshing sleep which lasted, with a single awakening, until morning, and the improvement the patient obtained was most striking.

One case of mitral regurgitation with leucocythemia and nervous exhaustion improved more rapidly on this food than on all other measures combined. In cases of nervous exhaustion and brain tire, its effects are most marked, as we have experienced many times in the past five years in the frequent personal use of the agent. It contains the principles of pure, healthy blood and nerve tissue ready for immediate assimilation. Fourteen per cent. of the entire quantity is uncoagulated albumen, as we have demonstrated by actual analysis.

We have tided babies over critical periods often with a few drops in its usual diet. We have given it to dipsomaniacs with or without non-alcoholic stimulants with superb results. The sole objection our patients have to it is its odor. Its taste is not disagreeable; it has the odor and appearance of blood. All objections are soon forgotten, however, in the results of its action upon the nutrition of the system, and the patient soon learns to like it, and often craves for it, drinking it from the bottle or a glass readily, like any beverage. It ought to be the food par-excellence for rapid appropriation in all conditions of exhaustion.

P. S.—Phosphates act well with the Liquid Food.

Editorial of the Chicago *Medical Times*, June, 1890.

In 97% of all cases where mother's milk is scanty or poor a copious flow of rich milk will be caused in 3 days by giving the mother "nutrolactis". Using this remedy mothers become stronger, infants thrive notably. Try it Doctor

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1890—91.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. McKENNAN.

Business correspondence should be addressed to

PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

Woman's Medical College

OF BALTIMORE,

S. E. Cor. Druid Hill Ave. and Hoffman Street.

THE NINTH REGULAR SESSION WILL BEGIN OCTOBER 1ST, 1890, and continue seven months. For further information or catalogue, apply to

RANDOLPH WINSLOW, M. D., Dean,

No. 1 Mount Royal Terrace, Baltimore, Md.

COLLEGE OF PHYSICIANS AND SURGEONS

OF BALTIMORE, Md.

The Preliminary Course will begin September 15, 1890.

The Regular Session will open October 1, 1890, and close April 1, 1891. For catalogue containing full information, write to

THOMAS OPIE, M. D., DEAN,

N. W. Cor. Calvert and Saratoga Streets,

13t. Baltimore, Md.

COLLEGE OF MEDICINE. SYRACUSE UNIVERSITY.

FACULTY.

JOHN VAN DUYN, M. D., Surgery.
HENRY D. DIDAMA, M. D., Practice and Clinical Medicine.
WILLIAM T. PLANT, M. D., Diseases of Children.
ALFRED MERCER, M. D., State Medicine.
WILLIAM MANLIUS SMITH, M. D., Chemistry.
DAVID M. TOTMAN, M. D., Clinical Surgery,
NATHAN JACOBSON, M. D., Clinical Surgery and Laryngology.
GAYLORD P. CLARK, M. D., Anatomy.
WILLIAM H. DUNLAP, M. D., Dermatology.
JOHN L. HEFFRON, M. D., Materia Medica and Therapeutics.
HENRY B. ALLEN, M. D., Obstetrics.
A. CLIFFORD MERCER, M. D., Pathology.
HENRY L. ELSNER, M. D., Clinical Medicine.
FRANK W. MARLOW, M. D., Ophthalmology.

Three Years' Graded Course. Year begins October 7th, 1890, ends in June, 1891.

FIRST YEAR: Anatomy, Physiology, Chemistry, Histology, Materia Medica.

SECOND YEAR: Anatomy, Physiology, Chemistry, Therapeutics, Pathology, Practice, Surgery, Clinical Medicine and Surgery.

THIRD YEAR: Therapeutics, Practice, Surgery, Children, Clinics, Obstetrics, Gynæcology, Forensic Medicine, Ophthalmology, Hygiene.

An experience of seventeen years has demonstrated that a three years' graded course is superior in every respect to an ungraded, unnatural, and cramming course of two winters.

Tuition, $80.00 for each Year. Perpetual Ticket, $200.00. Diploma, $25.00.

For circulars with full information, address

W. H. DUNLAP, M. D., Registrar, SYRACUSE, N. Y.

UNIVERSITY OF MARYLAND

SCHOOL OF MEDICINE.

Eighty-fourth Annual Announcement, 1890–91. The next regular session will begin October 1st, 1890. A full course of didactic lectures, with ample clinical and dissecting-room facilities.

FACULTY:

GEORGE W. MILTENBERGER, M. D.,
Emeritus Professor of Obstetrics, and Honorary President of the Faculty.

CHRISTOPHER JOHNSON, M. D.,
Emeritus Professor of Surgery.

SAMUEL C. CHEW, M. D.,
Professor of Principles and Practice of Medicine and Hygiene.

FRANK DONALDSON, M. D.,
Emeritus Clinical Professor of Diseases of the Throat and Chest.

WILLIAM T. HOWARD, M. D.,
Professor of Diseases of Women and Children and Clinical Medicine.

JULIAN J. CHISOLM, M. D.,
Professor of Eye and Ear Diseases.

FRANCIS T. MILES, M. D.,
Professor of Physiology and Clinical Professor of Diseases of Nervous System.

LOUIS McLANE TIFFANY, M. D.,
Professor of Surgery.

J. EDWIN MICHAEL, M. D.,
Professor of Obstetrics.

I. EDMONSON ATKINSON, M. D.,
Professor of Materia Medica and Therapeutics, Clinical Medicine and Dermatology.

R. DORSEY COALE, PH. D.,
Professor of Chemistry and Toxicology.

JOHN NOLAND MACKENZIE, M. D.,
Clinical Professor of Diseases of the Throat and Nose.

Professor of Anatomy.

Demonstrator of Anatomy.

For catalogue and further information, address: **Dr. I. E. ATKINSON, Dean, 605 Cathedral Street.**

DENTAL DEPARTMENT.

Ninth Annual Announcement. Next regular session begins October 1st, 1890. New and excellent Infirmary and Laboratory, with abundance of clinical material.

FACULTY:

FRED. J. S. GORGAS, M. D., D.D. S.,
Professor of Principles of Dental Science, Dental Surgery, and Dental Mechanism.

JAMES H. HARRIS, M. D., D.D. S.,
Professor of Operative and Clinical Dentistry.

I. EDMONSON ATKINSON, M. D.,
Professor of Materia Medica and Therapeutics.

FRANCIS T. MILES, M. D.,
Professor of Physiology.

L. McLANE TIFFANY, M. D.,
Clinical Professor of Oral Surgery.

Professor of Anatomy.

R. DORSEY COALE, PH. D.,
Professor of Chemistry.

JOHN C. UHLER, M. D., D.D. S.,
Demonstrator of Mechanical Dentistry.

CHAS. L. STEEL, M. D., D.D. S.,
Demonstrator of Operative Dentistry.

Demonstrator of Anatomy.

AND EIGHT ASSISTANT DEMONSTRATORS.

For catalogue and other information, apply to **Dr. F. J. S. GORGAS, Dean, 845 Eutaw Street, Baltimore.**

Philadelphia Polyclinic and College for Graduates in Medicine.

THE POLYCLINIC HOSPITAL, NORTHWEST CORNER BROAD AND LOMBARD STS.

PROFESSORS:

Emeritus Professor of Surgery—R. J. LEVIS, M. D.
Emeritus Professor of Diseases of the Throat—J. SOLIS-COHEN, M. D.
Emeritus Professor of Diseases of the Ear—CHARLES H. BURNETT, M. D.
Emeritus Professor of General and Orthopædic Surgery, CHARLES B. NANCREDE, M. D.
Applied Anatomy and Operative Surgery—JOHN B. ROBERTS, M. D.
Diseases of the Mind and Nervous System—CHARLES K. MILLS, M. D.
Clinical Chemistry and Hygiene—HENRY LEFFMANN, M. D.
Diseases of the Skin—ARTHUR VAN HARLINGEN, M. D.
Diseases of the Eye—GEORGE C. HARLAN, M. D.
Genito-Urinary and Venereal Diseases—J. HENRY C. SIMES, M. D.
Gynæcology—B. F. BAER, M. D.
Operative Surgery—LEWIS W. STEINBACH, M. D.
Diseases of the Chest—THOMAS J. MAYS, M. D.
Diseases of Throat and Nose—ALEXANDER W. MACCOY, M. D.
Orthopædic Surgery—H. AUGUSTUS WILSON, M. D.
Diseases of the Eye—EDWARD JACKSON, M. D.
Clinical Medicine and Applied Therapeutics—SOLOMON SOLIS-COHEN, M. D.
Diseases of the Mind and Nervous System—S. WEIR MITCHELL, M. D., LL. D.
Diseases of the Ear—B. ALEX. RANDALL, M. D.
Obsetrics and Diseases of Children—EDW. P. DAVIS, M. D.
Orthopædic Surgery—THOMAS G. MORTON, M. D.
Clinical Surgery—THOMAS S. K. MORTON, M D.
Experimental Therapeutics and Physiology—THOMAS J. MAYS, M. D.

Practical individual instruction, Clinical and Demonstrative, to physicians only, during the entire year. Fee for any one branch for six weeks, **$15 00**; General Ticket for twelve Clinical branches, **$100.00**; Tickets good for one Clinic weekly for three months, issued on application. For Announcement, with full particulars of CLINICAL AND LABORATORY COURSES, address

S. SOLIS-COHEN, M. D., Secretary.

MEDICO-CHIRURGICAL COLLEGE

OF PHILADELPHIA.

WINTER SESSION will begin Wednesday, October 1st, and continue until April 16th. PRELIMINARY SESSION begins September 8th. SPRING TERM, April 20th, 1891.

The curriculum is graded, and a preliminary examination and three Annual Winter Sessions are required. Laboratory instruction in Chemistry, Histology, Pathology, Hygiene, Physiology, with Bedside instruction in Medicine, Surgery and Gynecology, is a part of the regular course.

Fees: Matriculation $5.00. First and second years, each $75.00. Third year $100.00. Fourth year free to those in attendance three sessions; to all others $100.00.

For Announcement or information apply to

E. E. MONTGOMERY, M. D.,

1818 Arch Street, Philadelphia, Pa.

THE JEFFERSON MEDICAL COLLEGE

OF PHILADELPHIA.

The 66th Annual Session of the Jefferson Medical College begins October 1st and continues nearly 7 months. Preliminary Lectures will be held from 22d of September.

EACH student is immediately and personally taught in Obstetrics and Gynæcology, Physical Diagnosis, Laryngology, Ophthalmology, Medical Chemistry, Pharmacy, Materia Medica, and Experimental Therapeutics, Histology and Experimental Physiology, Minor Surgery, Bandaging, Operations on the Cadaver, Pathology, Neurology, and Electro-Therapeutics.

Three annual regular sessions are required. Bedside instruction in Medicine, Gynæcology, Surgery and Obstetrics is a part of the third year course. No extra fee.

The **Annual Announcement** will be sent on application to **J. W. HOLLAND, M. D., Dean.**

NATIONAL MEDICAL COLLEGE.

MEDICAL DEPARTMENT OF THE

COLUMBIAN UNIVERSITY,

WASHINGTON, D. C.

The 68th Annual Session will begin October 7th and end March 1st. Graded three years' course required. Women admitted. Professors: J. F. Thompson, W. W. Johnston, A. F. A. King, E. T. Fristoe, Wm. Lee, D. W. Prentiss, D. K. Shute.

For circulars, address

A. F. A. KING, M. D., DEAN, 726 THIRTEENTH ST., N. W., WASHINGTON D. C.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 125TH ANNUAL WINTER SESSION will begin Wednesday, October 1st, 1890, at 12 M., and will continue seven months. The PRELIMINARY SESSION begins September 22d, 1890, the Spring Term early in May, 1891.

The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D., LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.
JAMES TYSON, M.D., Professor of Clinical Medicine.
HORATIO C. WOOD, M.D., LL.D., Professor of Materia Medica, Pharmacy and General Therapeutics.
THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry and Toxicology.
JOHN ASHHURST, JR., M.D., Professor of Surgery and of Clinical Surgery.
EDWARD T. REICHERT, M.D. Professor of Physiology.
WILLIAM F. NORRIS, M.D., Honorary Prof. of Ophthalmology
BARTON COOKE HIRST, M.D., Professor of Obstetrics.
J. WILLIAM WHITE, M.D., Professor of Clinical Surgery.
JOHN GUITÉRAS, M.D., Professor of General Pathology and Morbid Anatomy.
GEORGE A. PIERSOL, M.D., Professor of Histology and Embryology.
SAMUEL G. DIXON, M.D., Professor of Hygiene.

For Catalogue and announcement containing particulars, apply to

DR. JAMES TYSON, Dean,
36th and Woodland Avenue, Philadelphia.

Requires No Cooking.

Liebig demonstrated that the best substitute for normal human milk was not the milk of any animal, but a combination of animal milk with the elements of those grains which are used in repairing waste, building tissues, and generating heat.

Mellin's Food

Dissolved in hot water and milk, according to the directions, is the genuine Liebig's Food, and promotes in infants a healthy growth, a full development, and a vigorous constitution. *It requires no cooking.*

DOLIBER-GOODALE CO., BOSTON, MASS.

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y.

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

PLANTEN'S

CAPSULES

Known over 50 years for "General Excellence."

H. PLANTEN & SON, Established 1836. New York.

SOFT AND HARD CAPSULES FILLED OF ALL KINDS.

Nine sizes: 3, 5, 10, and 15 Min., and 1, 2½, 5, 10, and 15 Gram.

SPECIALTIES:—Sandal Pure, Compound Sandal, Apiol, Erigeron, Creosote, etc.

IMPROVED EMPTY CAPSULES.

POWDERS, 8 sizes; LIQUIDS, 8 sizes; RECTAL, 3 sizes; VAGINAL, 9 sizes; HORSE, 6 sizes; VETERINARY RECTAL, 3 sizes.

CAPSULES FOR MECHANICAL PURPOSES.

New Articles, and Capsuling Private Formulæ a Specialty.

SOLD BY ALL DRUGGISTS. SAMPLES FREE.

Specify PLANTEN'S on all Orders.

Medical Department, State University of Iowa,

AT IOWA CITY, IOWA.

The next session will begin on September 10th, 1890, and continue until March 11th, 1891.

Attendance upon three courses of lectures, of six months each, is requisite to graduation. Facilities for dissection and clinical study are unsurpassed.

Term Expenses:—Lecture Ticket, $20.00; Demonstrator's Ticket, $10.00; Matriculation Ticket, $5.00 (paid but once); Hospital Ticket, $3.00; Examination Fee (for final examination), $25.00. No charge for dissecting material.

For further information, address

DR. L. W. LITTIG, Secretary, Iowa City, Iowa.

"What a boon it would be to the Medical Profession if some reliable Chemist would bring out an Extract of Malt in combination with a well-digested or peptonized Beef, giving us the elements of Beef and the stimulating and nutritious portions of Ale."—J. MILNER FOTHERGILL, M.D.

Ale & Beef

"PEPTONIZED"

(EXTRACT:—BOVIS CUM MALTO.)

's the identical combination suggested by the late eminent Fothergill.

EACH BOTTLE REPRESENTS 1-4 POUND
OF LEAN BEEF THOROUGHLY PEPTONIZED.

It is the only Mild Stimulant combined with a Perfect Food known. It is very palatable, aids digestion, is retained by the most delicate stomach, and the purity of its ingredients is guaranteed.

THE "PEPTONIZED" BEEF

is manufactured by Prof. Preston B. Rose, of Chicago, late of the faculty of the University of Michigan.

THE ALE USED
IS THE PUREST AND BEST MADE IN AMERICA

Especially brewed for this purpose, and guaranteed to be equal to the best imported ales, as only the best Canada Malt and the choicest new hops are used in its manufacture.

IT IS A REAL FOOD; NOT A MERE STIMULANT,

as it contains all the albumen and fibrin of the beef as well as the nutritive qualities of the malted barley.

It is most useful during the period of Gestation, in allaying all vomiting, and invaluable to Nursing Mothers; also in Typhoid Fever and Dysentery.

Prof. G. A. Liebig says: "A careful chemical examination of the Peptonized Ale and Beef shows a much larger per cent. of nitrogenous blood and muscle-making matter over all other malt extracts, and that it is also rich in Diastase, giving it the power to digest Starch Foods."

We claim for our Hypodermic Tablets:

Absolute Accuracy of Dose.
Ready and Entire Solubility.
Perfect Preservation of the Drug.

Their convenience and utility will at once be apparent on examination.

They are put up in Cylindrical Tubes, convenient for carrying in Hypodermic or Pocket case, ten tubes in a box, with twenty tablets in each tube.

NOTE.—It will only be necessary in ordering to specify the numbers, as above. Wyeth's Manufacture. These Tablets will be sent by mail, on receipt of the proper amount.

PHILADELPHIA, PA.

Doctor:

You find the hot weather very exhaustive to your consumptive patients, don't you?

Have you ever thought of the reason why?

It is simply because the salts of the tissues are wasted in excessive perspiration.

How can you restore this waste? By administering quinine, iron, strychnine, manganese and all the range of exciting tonics? Not at all.

That only increases the difficulty and hastens the end.

There is but one way to give permanent improvement, and that is to restore the waste to the tissues by administering the hypophosphites of lime and soda, *chemically pure*. This will not only restore the waste but will also check most of it by restoring sufficient tone to the tissues to restrain the unnecessary perspiration. By this means you can make this a season of grateful refreshment to these afflicted ones, and, by taking advantage of the freedom from colds which the season brings, start them on the way to permanent recovery.

These are clinical facts, not theory.

McArthur's Syrup of Hypophosphites is the only one in the market consisting of the *chemically pure* hypophosphites of lime and soda.

If there is special indication for any other medicinal agent it can easily be added to the prescription.

What are the other conditions requiring the remedy, and which are rapidly cured by it? Scrofulosis, Rachitis, Chronic Cough, Chronic Bronchitis, Chronic Alcoholism, Impotence, Spermatorrhea, Nervousness, General Debility, Brain Exhaustion, Loss of Memory, Chronic Diarrhœa, Teething, Summer Diarrhœa, Suppurating Discharges, and Sores, Uterine Fibroids and all disorders of waste or faulty nutrition.

See that you get that which is absolutely pure and genuine. Write your prescriptions thus:

Syr: Hypophos: Comp: McArthur. One Bottle.

A large bottle will be sent you free (excepting express charges) if you will send your professional card or letter head. Address,

McARTHUR HYPOPHOSPHITE CO.,
BOSTON, MASS.

The Model Ledger

enables a physician to make out his bills with great ease. Beside this, it tells at a glance just how much he has earned in any quarter; how much he has received; and how much is still due him. These are all good things for a doctor to know.

ARISTOL.

ARISTOL, a combination of iodine and thymol, manufactured by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, Germany, is a valuable, inodorous and non-toxic antiseptic remedy, said to be superior to Iodoform, Iodole and Sozo-Iodole.

ARISTOL is insoluble in water and glycerine, and very sparingly in alcohol, but is very easily soluble in ether and chloroform. The ether solution is precipitated by the addition of alcohol. ARISTOL is very freely soluble in fatty oils. The solution must be made in the cold, by stirring, as the use of heat causes a decomposition. For the same reason it is necessary to protect the body from light and keep it in opaque bottles. It very readily adheres to the skin, and can thus be used as a powder strewn over wounds and burns.

In cases of mycosis it also acts well, and more quickly than any other known remedy, and does not cause irritation, like so many drugs.

The effective use of ARISTOL in psoriasis is of great interest, as our Materia Medica has hitherto supplied us with no non-poisonous drug, save only chrysarobin, the use of which is associated with a deep skin coloration and conjunctivitis—drawbacks from which ARISTOL is absolutely free.

In cases of lupus it is said to surpass even the best known remedies.

The value of ARISTOL can scarcely be over-estimated, as we have in it a drug possessing the good properties of Iodoform, but free from its toxic qualities. Its freedom, too, from any suspicious odor will be at once appreciated, both by the physician and his patient.

ARISTOL, prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, is supplied by us in ounces.

SULFONAL-BAYER.

The value of Sulfonal in children's diseases.—Dr. William C. Wile sent a paper with this title to the American Medical Association, in which he stated that Sulfonal was the ideal hypnotic. It was without the bad effects of opium and the uncertainty of the bromides. It could be given in ten-grain doses. It quieted reflex irritability. It did not constipate nor disturb the stomach. In one case in which a drachm was taken accidentally in ten-grain doses, there was a deep slumber lasting twenty-four hours, slight fever, but a normal pulse and respiration.—*Medical Record*, New York.

Dr. Henry M. Field, in a paper presented to the American Medical Association, says:—"Clinically observed, we recognize in Sulfonal a mild calmative, *a slowly, but progressively acting hypnotic;* it has no other action, and its operation is attended by no complications, near or remote. It is therefore a pure hypnotic, and, we submit, it is the only pure hypnotic we possess, up to date."—*New England Medical Monthly.*

Sulfonal-Bayer, prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, is supplied by us in ounces and in the form of Tablets of 5, 10 and 15 grains, put up in bottles of 10 and 100 tablets each.

We also offer Sulfonal-Bayer in the form of our soluble pills, containing 5 grains each.

PHENACETINE-BAYER.

Phenacetine in Insomnia.—Dr. F. Peyre Porcher, of Charleston, S. C., writes: "I desire to call special attention to the extreme value of Phenacetine as a remedy for insomnia. Given at night in a little water it is tasteless, innocuous, and induces sleep. I am confident, also, after repeated trials, that it is the best and most unobjectionable substitute for morphia. It causes sleep when, of course, pain is in abeyance, unless the pain be more than ordinary, and morphia hypodermically may then be required. The remedy may be repeated and the dose increased to seven or ten grains.

"Suffering from chronic rheumatism of the forearm, I have tested it repeatedly in my own person, and have given it to many who have suffered from insomnia, or inability to sleep from any transient cause, fatigue, nervousness, excitement, etc., in either sex." * * * * *—*Medical Record*, New York.

Phenacetine-Bayer, prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, is supplied by us in ounces and also in the form of our soluble pills and compressed tablets, containing two, four and five grains each. Either form may be obtained of any reputable apothecary.

It gratifies us to be able to announce that PHENACETINE, SULFONAL and SALOL have been incorporated into the new German Pharmacopœia just issued, and have been proposed by the General Medical Council of Great Britain for introduction into the forthcoming Addendum to the British Pharmacopœia. This action confirms and endorses our judgment in introducing these valuable remedies to the medical profession of the United States, and is a natural sequence of the favorable results experienced in their employment, and of the brilliant and conclusive testimony thereof, which had been so freely furnished by the most talented of the profession both in Europe and in the United States.

W. H. Schieffelin & Co.,

170 & 171 William Street,

NEW YORK.

ESTABLISHED 1855.

DRS. STRONG'S SANITARIUM,

SARATOGA SPRINGS, NEW YORK,

Receives persons recommended to it by their home physicians for Treatment, Change, Rest or Recreation, and places them under well-regulated hygienic conditions so helpful in the treatment of chronic invalids or the overtaxed.

For Treatment: In addition to the ordinary remedial agents, it employs Turkish, Russian, Roman, Sulphur, Electro-Thermal, the French Douche (Charcot's), and all Hydropathic Baths; Vacuum Treatment, Swedish Movements Massage, Pneumatic Cabinet, Inhalations of Medicated, Compressed, and Rarefied Air, Electricity in various forms, Thermo-Cautery, Calisthenics, and Saratoga Waters, under the direction of a staff of educated physicians.

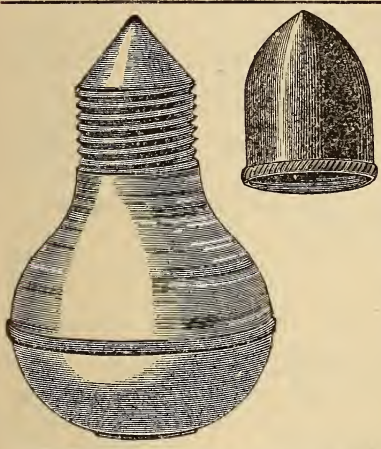
For Change: This Institution is located in a phenomenally dry, tonic, and quiet atmosphere, in the lower arc of the Adirondack Zone, and within the "Snow Belt."

For Rest: The Institution offers a well-regulated, quiet home, heated by steam and thoroughly ventilated, with cheering influences and avoiding the depressing atmosphere of invalidism.

For Recreation: To prevent introspection, are household sports at all seasons of the year, and in Winter, tobogganning, elegant sleighing, etc.; in Summer, croquet, lawn-tennis, etc.

Private professional references furnished upon application. Physicians are invited to inspect the Institution at their convenience. A liberal discount to physicians and their families.

For further information, address, DRS. S. S. & S. E. STRONG.



THE P.P.P. SYRINGE

Is universally considered the most perfect urethral Syringe in the market, because it combines within itself all desirable qualities. It measures but 1½ x 2¾ inches, has a capacity of fully half an ounce, and is made of one piece of soft rubber with conical point. To protect this soft point and to prevent pocket dust from getting into the Syringe, a Hard Rubber cap screws air-tight over it and enables the patient to carry it in his pocket filled with the injection ordered, ready for use when away from home.

For sale by all druggists.

THE GOODYEAR RUBBER CO.,

49 MAIDEN LANE, NEW YORK.

A Phosphorized Cerebro-Spinant

(FRELIGH'S TONIC).

FORMULA.

Ten minims of the Tonic contain the equivalents (according to the formulæ of the U. S. P., and Dispensatory) of

Tinct. Nux Strychnos,	1 minim.
" Ignatia Amara,	1 "
" Cinchona,	4 "
" Matricaria,	1 "
" Gentian,	½ "
" Columbo,	½ "
" Phosphorus, C. P.,	1-300 gr.
Aromatics,	2 minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

I. O. WOODRUFF & CO.,

Manufacturers of Physicians' Specialties,

No. 88 Maiden Lane, New York City.

LENTZ'S ASEPTIC COMPACT OPERATING SET, No. 10.

We have from time to time made improvements to this set and are now making a perfect aseptic set, which offers especial facilities for aseptic precautions; the blades are soldered into hollow German-silver handles, nickel-plated, are light so as not to be unwieldy and admit of a firm grasp when operating.

The saw is adjusted to the handle on an entirely new principle, being made to separate easily and to facilitate thorough cleansing.

The handle is entirely of metal and fenestrated to overcome unnecessary weight.

Scissors and Forceps having French locks can be separated, and the slide can be easily removed from Artery and Needle Forceps.

Therefore, no opportunity is offered for the lodgment and development of germs.

The entire set is patterned with especial reference to facility in cleansing.

The instruments can be sterilized by placing them in boiling water, without fear of damaging them. Wood or rubber handles will not admit of this procedure. For price, see case A.

The following instruments are put up in either a fine Mahogany or Morocco case, with nickel trimmings, lined with velvet, and has an extra space for Trephine with handle, and Elevator if desired.

One Amputating Knife (6 in. blade); One Finger Knife; One Hernia Knife; One Sharp Curved Bistoury; Two Scalpels; One Tenotome; One Tenaculum; One Pair Scissors, curved or flat; One Saw (9 in. blade); One Liston's Bone Forceps, with Spring; One Artery and Needle Forceps, improved; One Esmarch's Flat Rubber Tourniquet, with Chain; One Hæmostatic Forceps; One Director, with Aneurism Needle; Two Silver Probes; Silk, Wire, Wax and Needles.

With the Sixteen Instruments Contained in this Case, any Ordinary Operation may be Performed.

SIZE, 11 INCHES LONG, 4 INCHES WIDE, 2 INCHES HIGH.

A.—German Silver aseptic Handles on Knives and Saw, ... $34 00
B.—Hard Rubber aseptic Handles on Knives and Saw, ... 29 00
C.—Ebony Handles on Knives and Saw (as shown in illustration), ... 25 00
Either Set, with Trephine and Elevator in addition, ... 4 65

Gymnasium Department.

From this time henceforth the **Gymnasium** in all its important details will be a department in our business to which we shall devote especial attention.

With the addition to our own valuable patents, those of the **A. J. Reach Company,** of Philadelphia, recently purchased by us, enables us to claim the most **extensive department** of **Gymnasium Appliances in the world.**

We have been encouraged in this **important** movement by the constantly increasing demand from **Colleges, Seminaries,** and other **Educational** Institutions for Gymnasium Supplies, and henceforth we shall devote special attention to furnishing **plans, specifications,** and **estimates** to such and for **private residences** as well, and solicit correspondence with all contemplating the introduction of gymnastics for any purpose.

The Peerless Pulley Weight, illustration of which appears on this page, is a most perfect appliance for the development of the **chest** and **arms,** adjustable to the height of *any* person, and in weight from five to thirty pounds. For **man or woman** this is the peer of any method yet devised, especially for home use. Realizing the attention the **medical profession** and the **teacher,** are now giving to **healthful** exercise in **schools,** we solicit also their correspondence, and any orders, or business proceeding from such, will be gratefully received, and entitled to our best rates of discount, and will receive prompt and careful attention.

Visitors to our different establishments at **Chicago, New York,** and **Philadelphia** will always be welcome and politely served by the many efficient salesmen constantly in attendance.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the three Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the three Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.

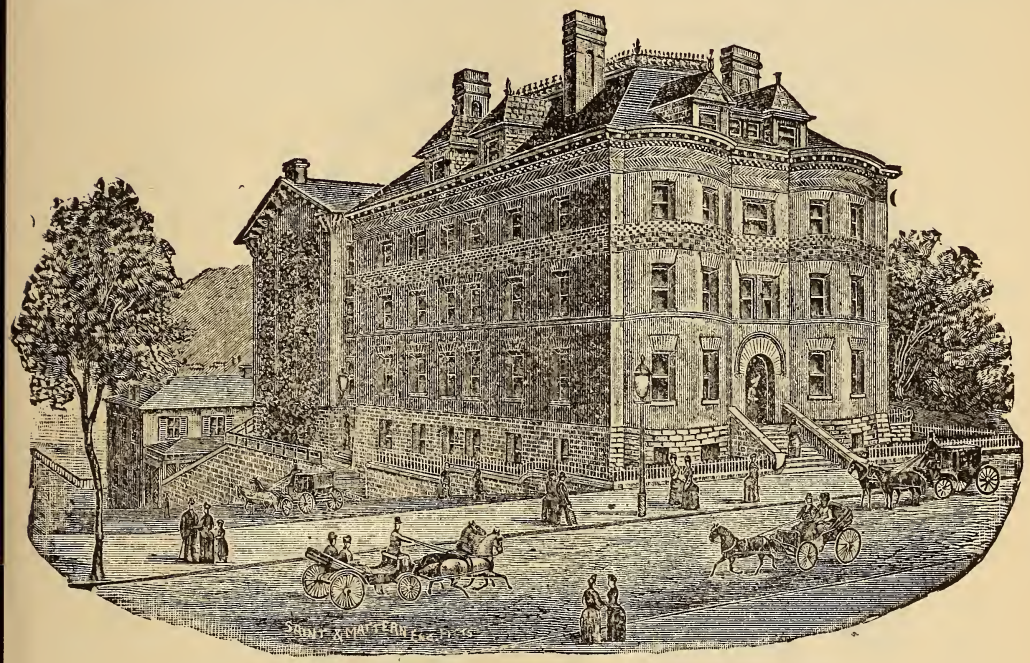
DR. R. S. SUTTON'S

Sanatorium for Diseases of Women.



Eighth Year Opens September 1, 1890.

ALLEGHENY CITY, PA.

This Institution is located on high ground, and overlooks the Allegheny, Monongahela and Ohio rivers; it commands a view of the city of Pittsburgh, and its picturesque surroundings. The building is large and beautiful, it is provided with every modern convenience, the halls are heated by steam, the rooms are commodious, well lighted and ventilated, and heated by open grates. The house is provided with a private parlor and reading-room for patients. The dining-room is large, handsomely finished, and furnished with small tables, securing privacy at meals for those who do not care to have meals served in their own rooms. Patients can be as secluded, should they desire it, as in a well appointed hotel. Each patient is examined by Dr. Sutton, and receives his daily personal attention, while Dr. J. H. Williamson, a physician of ample hospital experience, resides in the Institution, and has, under Dr. Sutton, the immediate care of the patients. The Institution accommodates 25 patients, and is equal in comfort to the best hotels.

Electricity, baths, douches, massage, local treatment, general medication and surgical operations are resorted to according to the requirements of each patient.

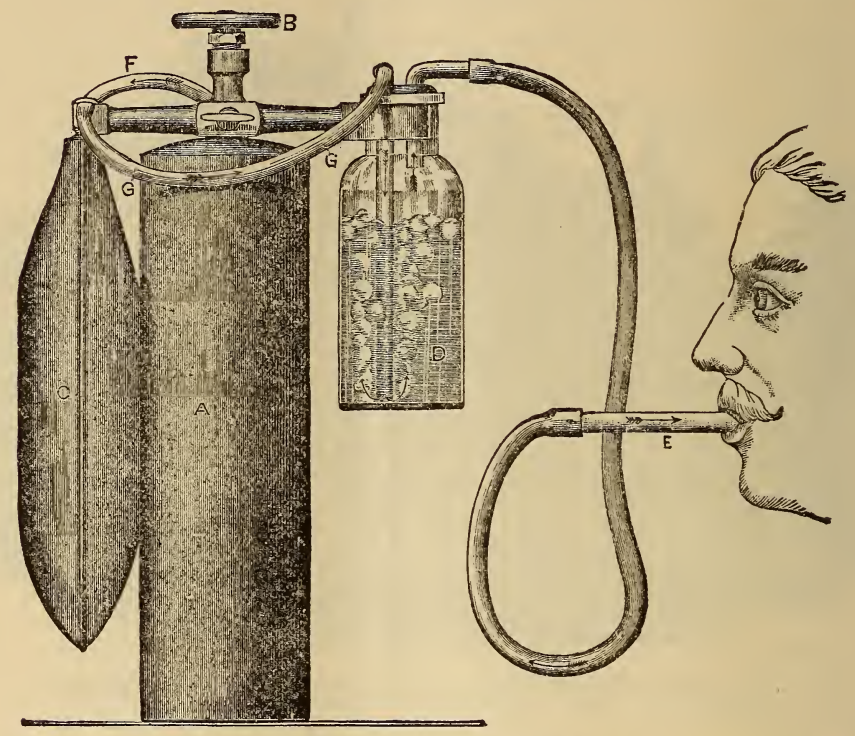
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.
LAMBERT'S
LITHIATED HYDRANGEA
KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request:

LAMBERT PHARMACAL CO., ST. LOUIS, MO.

FRENCH'S
COMPRESSED ANTISEPTIC PASTILLES.
(Dr. CARL SIELER'S FORMULÆ.)

FOR MAKING ANTISEPTIC SPRAYS, NASAL WASH, MOUTH WASH, Etc.

One tablet dissolved in four tablespoonfuls of warm water makes a solution which can be used as a spray or wash.

Supplied in bottles of 50, 100 and 1 lb.

COMPRESSED ANTISEPTIC TABLETS.
(FOR EXTERNAL USE.)

Each tablet contains:

7.3 grains . . . . . Hydrarg. Bichlor.
7.7 grains . . . . . Ammon. Clor.

One tablet dissolved in one pint of water will make a 1 to 1,000 solution, containing one part of Corrosive Sublimate in 1,000 parts of water.

Supplied in screw-cap bottles, containing 25 and 100 tablets each, and pounds.

FRENCH'S
COMPRESSED SULPHUR and CREAM OF TARTAR TABLETS.

An alterative and mild laxative for children and invalids. They are pleasantly flavored and sweetened, and form an agreeable method of medication.

FORMULA:

Sulphur Lotum, U. S. P. . . . . grs. v.
Potass. Bitart., pur. . . . . grs. xv in each tablet.

Put up in metal screw-cap glass jars, containing 35 tablets each. Also in 1 lb. bottles.

A sample of any of these preparations will be mailed to physicians free of charge, on application.

FOR SALE BY THE RETAIL DRUG TRADE GENERALLY.

FRENCH, RICHARDS & CO., Philadelphia, Pa.

To PHYSICIANS.

THE FOREMOST COCOA OF EUROPE
THE COMING ONE OF AMERICA.

VAN HOUTEN'S
"Best and Goes Farthest."

Physicians will do well in recommending, as their European colleagues do, VAN HOUTEN'S COCOA for daily family use. Now that the profession is deprecating the habitual use of alcoholic liquors, and as even tea and coffee are found too exciting for many temperaments—to say nothing of the growing number of cases of nervous disorder in this age of hot haste and feverish anxiety—the question of what beverage may be recommended, as at once refreshing and innocuous, is assuming the highest importance.

VAN HOUTEN'S
Most Appetizing. Easily Digested.

Cocoa has long been known as a useful article of diet, and its claims are steadily winning recognition. Unlike tea or coffee, it is not only a stimulant but a nourisher; and it has the great advantage of leaving none of their narcotic effects on the system. For this reason it is adapted to general use. The strong may take it with pleasure, and the weak with impunity.

VAN HOUTEN'S
The Original—Most Soluble.

"Pure soluble cocoa" is an invention of Mr. C. J. Van Houten, who patented this invention in Holland. Thus all other "pure soluble cocoas" are imitations. The process of manufacturing Van Houten's cocoa is still, to-day, a secret of C. J. Van Houten & Zoon. Chemists and medical men of the highest standing say, universally, that their observation shows that the Van Houtens do exactly what science would suggest for the conversion of raw cocoa into a satisfactory article of food. They simply remove some of the originally contained fat, which is apt to disagree with the system, and in some ingenious manner, increase the solubility of flesh-forming constituents.

VAN HOUTEN'S
"Once Tried, Always Used."

To remove excess of fat is always desirable. Some manufacturers do this by largely diluting the ground cocoa with starch. A cupful of thick beverage may thus be made, which no doubt contains a diminished amount of fat, but of course also contains a diminished amount of every other constituent of the cocoa. For persons who desire a thick, starch-like beverage, such a mixture, miscalled "soluble" cocoa, may be unobjectionable, though the cocoa in it is less easy of digestion than Van Houten's preparation. A far better method, however, is to extract, as the Van Houtens do, one part of the fat from four of cocoa, and, as a consequence, render each of the valuable constituents remaining, one-third more effective than before. Instead of being weakened by starch, Van Houten's cocoa is thus made one-third stronger in every one of its valuable properties.

VAN HOUTEN'S
"Largest Sale in the World."

Requires No Cooking.

Liebig demonstrated that the best substitute for normal human milk was not the milk of any animal, but a combination of animal milk with the elements of those grains which are used in repairing waste, building tissues, and generating heat.

Mellin's Food

Dissolved in hot water and milk, according to the directions, is the genuine Liebig's Food, and promotes in infants a healthy growth, a full development, and a vigorous constitution. *It requires no cooking.*

DOLIBER-GOODALE CO., BOSTON, MASS.

"THIS IS AN AGE OF APOLLINARIS WATER."
—WALTER BESANT.

Apollinaris

"THE QUEEN OF TABLE WATERS."

The filling at the Apollinaris Spring (Rhenish Prussia), amounted to

11,894,000 BOTTLES IN **1887,**
12,720,000 BOTTLES IN **1888** AND
15,822,000 BOTTLES IN **1889.**

"The annual consumption of this favorite beverage affords a striking proof of the widespread demand which exists for table water of absolute purity, and it is satisfactory to find that, wherever one travels, in either hemisphere, it is to be met with; it is ubiquitous, and should be known as the cosmopolitan table water. 'Quod ab omnibus, quod ubique.'"—BRITISH MEDICAL JOURNAL.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

E. FOUGERA & CO., 30 North William St., New York.

Sole Agents for the above Preparations.

GARDNER'S

SYRUP OF HYDRIODIC ACID,

Introduced in 1878 by R. W. GARDNER.

The Reputation which Hydriodic Acid has Attained During the past Eleven Years was Won by this Preparation.

Numerous Imitations prepared differently, and weaker in Iodine, are offered, from the use of which the same therapeutic effects cannot be obtained.

Caution.—Use no Syrup of Hydriodic Acid which has turned red. This shows decomposition and free Iodine. In this state it acts as an irritant and fails to produce desirable results.

Unprincipled apothecaries substitute imitations when Gardner's Syrup is prescribed, and physicians, failing to get desirable and promised results, attribute the fault, unjustly, to Gardner's Syrup.

THERAPEUTIC INDICATIONS.

Hay Fever; Rose Cold; Poisoning by Lead, Mercury or Arsenic; Acute and Chronic Rheumatism; Asthma; Chronic Bronchitis; Catarrh; Congestion of Lungs in Children; Adenitis; Eczema; Lupus; Chronic Malarial Poisoning; Lumbago; Acute Pneumonia; Psoriasis; Scrofulous Diseases; Goitre; Enlarged Glands; Cold Abscesses; Indolent Sores; Excessive Fat; Fatty Degeneration of the Heart; to absorb non-malignant Tumors; and in the latter stages of Syphilis; Syphilitic Phthisis.

Details of treatment furnished physicians upon application to undersigned without charge.

Gardner's Chemically Pure Syrups of Hypophosphites.

Embracing the separate Syrups of Lime, of Soda, of Iron, of Potassa, of Manganese, and an Elixir of the Quinia Salt; enabling physicians to accurately follow Dr. Churchill's method, by which thousands of authenticated cases of Phthisis have been cured. The only salts, however, used by Churchill in Phthisis are those of Lime, of Soda, and of Quinia, and always separately according to indications,—never combined.

The reason for the use of single Salts is because of antagonistic action of the different bases, injurious and pathological action of Iron, Potassa, Manganese, etc., in this disease.

These facts have been demonstrated by thirty years' clinical experience in the treatment of this disease exclusively, by Dr. Churchill, who was the first to apply these remedies in Medical practice. Modified doses are also required in this disease; seven grains during twenty-four hours being the maximum dose in cases of Phthisis, because of increased susceptibility of the patient to their action, the danger of producing toxic symptoms (as hemorrhage, rapid softening of tubercular deposit, etc.), and the necessity that time be allowed the various functions to recuperate simultaneously; over-stimulation, by pushing the remedy, resulting in crisis and disaster.

A pamphlet of sixty-four pages, devoted to a full explanation of these details and others, such as contra-indicated remedies, indications for the use of each hypophosphite, reasons for the use of absolutely pure Salts, protected in Syrup from oxidation, etc., mailed to physicians without charge upon application to

R. W. GARDNER, 158 William St., N. Y. City.

W. H. SCHIEFFELIN & CO., Sole Wholesale Agents, New York.

CELERINA

NERVE TONIC, STIMULANT AND ANTISPASMODIC.

FORMULA.—Every Fluid Drachm represents FIVE grains EACH—Celery, Coca, Kola, Viburnum and Aromatics.

INDICATIONS.—Loss of Nerve-Power (so usual with Lawyers, Preachers, Writers and Business Men), Impotency, Spermatorrhea, Nervous Headache, Neuralgia, Paralysis, Hysteria, Opium Habit, Inebriety, Dyspepsia, and ALL LANGUID conditions of the System.

Indispensable to restore a patient after alcoholic excess.

DOSE.—One or two Teaspoonfuls three or more times a day, as directed by the Physician.

LIQUID IRON-RIO

Palatable and easily assimilated. Does not produce Nausea, nor irritate the Stomach. Does not Cause Headache, nor Constipate. Does not Stain the Teeth. It is so Acceptable to the Stomach that its Use is Admissible when all other forms of Iron would be rejected. Being so Readily Assimilable, it only requires a small Dose.

Each Fluid Drachm contains ONE GRAIN of Iron in a Pleasant and Digestible Form.

DOSE.—One or more Teaspoonfuls as indicated, during or after meals.

S. H. KENNEDY'S

CONCENTRATED EXTRACT OF

PINUS CANADENSIS

DARK. A NON-ALCOHOLIC LIQUID. WHITE.

A MOST VALUABLE NON-IRRITATING MUCOUS ASTRINGENT.

INDICATIONS.—Albuminuria, Diarrhea, Dysentery, Night-Sweats, Hemorrhages, Profuse Expectoration, Catarrh, Sore Throat, Leucorrhea, and other Vaginal Diseases, Piles, Sores, Ulcers, Burns, Scalds, Gonorrhea, Gleet, Etc.

When Used as an Injection, to Avoid Staining of Linen, the WHITE Pinus should be used.

RECOMMENDED BY PROMINENT EUROPEAN AND AMERICAN PHYSICIANS.

RIO CHEMICAL CO., St. Louis, Mo., U. S. A.

LONDON. PARIS. CALCUTTA. MONTREAL.

A CASE WITH A LESSON IN IT.

We have frequently referred to the necessity of keeping the pregnant woman supplied with those chemical substances which she must give to the child in the formation of its little frame, and the dire effects which may result from a deficiency of those substances. The headaches, neuralgias, spinal tenderness, and some of the many disorders of digestion, and even mental failure, may be all prevented or relieved by supplying to the mother the chemical food her system demands.

We have noticed a few cases where the most serious results have occurred to the mother by such a deficiency, one of which is well worth relating. Mrs. M., aged 30, pregnant with her third child, suffered from the second to the fifth month of her pregnant term with gradually failing strength and health, and nervous irritability. She was very restless nights for three or four days, the peculiar restlessness of complete nervous exhaustion, and was irrational for more than a week.

At this time I advised that she have a teaspoonful of Murdock's Liquid Food every hour in milk, and a little wine every four hours. The third night she had fifteen drops of hydrobromic acid dil. every three or four hours, which was continued for a week. The liquid food after a week every two hours, and all other medicines were discontinued. Her bowels were moved with a mild laxative at first, and afterward became regular. Her tongue cleaned quickly and her skin assumed a more natural appearance.

At this writing, less than three weeks from our first visit, the patient is able to sit up an hour at a time, is quite rational and cheerful, has a good appetite, the bowels are quite regular, there is no headache, and but little spinal tenderness. She sleeps reasonably well if fed frequently. She is allowed to suit her taste in her diet. The child is quite active, and the mother is progressing so nicely that it is hoped that she will pass safely through her confinement, which is nearly at hand. She will be kept on the liquid food and the phosphates until her confinement after which, the condition will suggest the treatment. This is the most marked case of a starved nervous system we have ever seen, and the benefit derived from the treatment proves the theory as to the cause of the trouble.

Apropos with the above, comes the question of the selection of nutritious foods for those many cases which demand strong and immediate nourishment. The food used in the above case has produced marvelous results for us in some of those extreme cases in which we have used it.

In one case of nervous exhaustion the insomnia was absolutely painful. When the exhaustion forced the patient to sleep there was an immediate sense of falling or approaching death, or there were hallucinations which were appalling, rendering the nights unbearable. One teaspoonful of Murdock's Liquid Food so nourished the system the first night it was given that the patient sank into a quiet, refreshing sleep which lasted, with a single awakening, until morning, and the improvement the patient obtained was most striking.

One case of mitral regurgitation with leucocythemia and nervous exhaustion improved more rapidly on this food than on all other measures combined. In cases of nervous exhaustion and brain tire, its effects are most marked, as we have experienced many times in the past five years in the frequent personal use of the agent. It contains the principles of pure, healthy blood and nerve tissue ready for immediate assimilation. Fourteen per cent. of the entire quantity is uncoagulated albumen, as we have demonstrated by actual analysis.

We have tided babies over critical periods often with a few drops in its usual diet. We have given it to dipsomaniacs with or without non-alcoholic stimulants with superb results. The sole objection our patients have to it is its odor. Its taste is not disagreeable; it has the odor and appearance of blood. All objections are soon forgotten, however, in the results of its action upon the nutrition of the system, and the patient soon learns to like it, and often craves for it, drinking it from the bottle or a glass readily, like any beverage. It ought to be the food par-excellence for rapid appropriation in all conditions of exhaustion.

P. S.—Phosphates act well with the Liquid Food.

Editorial of the Chicago *Medical Times*, June, 1890.

In 97% of all cases where mother's milk is scanty or poor a copious flow of rich milk will be caused in 3 days by giving the mother "nutrolactis". Using this remedy mothers become stronger, infants thrive notably. Try it Doctor

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1890—91.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. McKENNAN.

Business correspondence should be addressed to

PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

Woman's Medical College

OF BALTIMORE,

S. E. Cor. Druid Hill Ave. and Hoffman Street.

THE NINTH REGULAR SESSION WILL BEGIN OCTOBER 1ST, 1890, and continue seven months. For further information or catalogue, apply to

RANDOLPH WINSLOW, M. D., Dean,

No. 1 Mount Royal Terrace, Baltimore, Md.

COLLEGE OF PHYSICIANS AND SURGEONS

OF BALTIMORE, Md.

The Preliminary Course will begin September 15, 1890.

The Regular Session will open October 1, 1890, and close April 1, 1891. For catalogue containing full information, write to

THOMAS OPIE, M. D., DEAN,

N. W. Cor. Calvert and Saratoga Streets,

13t. Baltimore, Md.

COLLEGE OF MEDICINE. SYRACUSE UNIVERSITY.

FACULTY.

FRANK W. MARLOW, M. D., Ophthalmology.

Three Years' Graded Course. Year begins October 7th, 1890, ends in June, 1891.

FIRST YEAR: Anatomy, Physiology, Chemistry, Histology, Materia Medica.

SECOND YEAR: Anatomy, Physiology, Chemistry, Therapeutics, Pathology, Practice, Surgery, Clinical Medicine and Surgery.

THIRD YEAR: Therapeutics, Practice, Surgery, Children, Clinics, Obstetrics, Gynæcology, Forensic Medicine, Ophthalmology, Hygiene.

An experience of seventeen years has demonstrated that a three years' graded course is superior in every respect to an ungraded, unnatural, and cramming course of two winters.

Tuition, $80.00 for each Year. Perpetual Ticket, $200.00. Diploma, $25.00.

For circulars with full information, address

ESTABLISHED 16 YEARS. BEWARE OF IMITATIONS.

COLDEN'S LIQUID BEEF TONIC

AN INVALUABLE AID IN MEDICAL PRACTICE.

ORIGINAL | COLDEN'S LIEBIG'S LIQUID EXTRACT OF BEEF AND TONIC INVIGORATOR. | LABEL.

ESSENTIALLY DIFFERENT FROM ALL OTHER BEEF TONICS. UNIVERSALLY ENDORSED BY LEADING PHYSICIANS.

This preparation, consisting of the Extract of Beef (prepared by Baron Liebig's process), the best Brandy obtainable, soluble Citrate of Iron, Cinchona and Gentian is offered to the Medical Profession upon its own merits. It is of inestimable value in the treatment of **Debility, Convalescence from Severe Illness Anæmia, Malarial Fever, Chlorosis, Incipient Consumption, Nervous Weakness.** and maladies requiring a Tonic and Nutrient. It is quickly absorbed by the Stomach and upper portion of the Alimentary Canal. and therefore finds its way into the circulation quite rapidly.

COLDEN'S LIQUID BEEF TONIC appeals to the judgment of intelligent Physicians in the treatment of

ALL CASES OF GENERAL DEBILITY.

By the urgent request of several eminent members of the medical profession, I have added to each wineglassful of this preparation two grains of Soluble Citrate of Iron, and which is designated on the label, **"With Iron, No. 1;"** while the same preparation, **Without Iron,** is designated on the label as **"No. 2."**

In prescribing this preparation, physicians should be particular to mention *"COLDEN'S,"* viz., *"Ext. Carnis Fl. Comp. (Colden)."* A Sample of **COLDEN'S BEEF TONIC** will be sent free on application, to any physician (enclosing business card) in the United States. *Sold by druggists generally.*

C. N. CRITTENTON, General Agent, 115 Fulton St., New York.

MEDICAL AND SURGICAL REPORTER,

P. O. Box 843, Philadelphia, Pa.

FELLOWS'
HYPO-PHOS-PHITES

(SYR: HYPOPHOS: COMP: FELLOWS)

Contains **The essential elements** to the Animal Organization—Potash and Lime.

The **Oxydizing Agents**—Iron and Manganese;

The **Tonics**—Quinine and Strychnine,

And the **Vitalizing Constituent**—Phosphorus,

Combined in the form of a Syrup, with *slight alkaline reaction.*

It Differs in Effect from all others, being pleasant to taste, acceptable to the stomach, and harmless under prolonged use.

It has Sustained a High Reputation in America and England for efficiency in the treatment of Pulmonary Tuberculosis, Chronic Bronchitis, and other affections of the respiratory organs, and is employed also in various nervous and debilitating diseases with success.

Its Curative Properties are largely attributable to Stimulant, Tonic, and Nutritive qualities, whereby the various organic functions are recruited.

In Cases where innervating constitutional treatment is applied, and tonic treatment is desirable, this preparation will be found to act with safety and satisfaction.

Its Action is Prompt; stimulating the appetite and the digestion, it promotes assimilation, and enters directly into the circulation with the food products.

The Prescribed Dose produces a feeling of buoyancy, removing depression or melancholy, and hence is of great value in the treatment of Mental and Nervous Affections.

From its exerting a double tonic effect and influencing a healthy flow of the secretions, its use is indicated in a wide range of diseases.

Prepared by JAMES I. FELLOWS, Chemist,

48 VESEY STREET, NEW YORK.

Circulars sent to Physicians on Application.

FOR SALE BY ALL DRUGGISTS.

MILK OF MAGNESIA.

A PURE HYDRATED OXIDE OF MAGNESIUM.—(MgH_2O_2.)

ANTACID AND CORRECTIVE.

Especially recommended in the Gastro-intestinal irritations of infant, child and adult life—Nausea—Vomiting in Pregnancy—Sour Stomach—Diarrhœa—Cholera Infantum—and the Rheumatic and Gouty conditions resulting from acid secretions.

This Hydrate presents Magnesia practically in solution without grittiness or precipitation—No danger from concretions as with the calcined—Free from Carbonic Acid—Miscible with other fluids—in a form easy of administration and absorption. Superior to lime water or chalk mixture for addition to milk. It is not a purge: but in antacid, corrective or mild laxative indications will be found reliable and safe. It combines well with Syrup Rhubarb—Soda—Opium—the various astringents, etc.

PHOSPHO-MURIATE OF QUININE,

COMPOUND,

A RELIABLE ALTERATO-CONSTRUCTIVE,

Particularly indicated in conditions of **disturbed nutrition** and **tissue retrograde.**

An easily appropriated general tonic, promoting digestion, and safe under prolonged use. A permanent combination of the soluble Wheat Phosphates, with Muriate of Quinine, Iron and Strychnia.

Of greater strength than the various Hypophosphite compounds.

The above are put up in Dispensing and Trade Containers.

DIGESTIBLE COCOA.
WHEAT PHOSPHATES.
COD LIVER OIL EMUL.

THE CHAS. H. PHILLIPS CHEMICAL CO.,
77 PINE STREET, NEW YORK.

CH. MARCHAND'S

Peroxide of Hydrogen,

MEDICINAL (ABSOLUTELY HARMLESS)

H_2O_2

is rapidly growing in favor with the medical profession. It is the most powerful antiseptic known, almost tasteless, and odorless. Can be taken internally or applied externally with perfect safety. Its curative properties are positive, and its strength and purity can always be relied upon. This remedy is not a nostrum.

Experiments of Prof. Pasteur, Dr. Koch, and many other scientific authorities, prove beyond doubt that Germs, Bacteria, or Microbes cause and develop: **NOSE, THROAT, AND LUNG DISEASES—Diphtheria, Croup, Sore Throat, Catarrh of the Nose, Hay Fever, Bronchitis, Laryngitis, Pharyngitis, Whooping Cough, Consumption and other Chronic Affections, specific or not.**

GERMS, BACTERIA, OR MICROBES are instantaneously annihilated when brought into contact with **Ch. Marchand's Peroxide of Hydrogen.** This wonderful bactericide acts both chemically and mechanically upon all excretions and secretions, so as to thoroughly change their character and reactions instantly. By destroying the microbian element this remedy removes the cause of the disease.

Prepared only by

CAUTION.—I would earnestly impress upon the profession the very great importance of prescribing only my Peroxide of Hydrogen (Medicinal), from which all hurtful chemicals have been eliminated.

By specifying in your prescriptions "Ch. Marchand's Peroxide of Hydrogen (Medicinal)," which is sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing my label and signature, you will never be imposed upon.

Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

A book containing full explanations concerning the therapeutical applications of **Ch. Marchand's Peroxide of Hydrogen (Medicinal),** with opinions of the profession, will be mailed to physicians free of charge on application.

¼ lb. bottle, retail, 35 cents; ½ lb. bottle, retail, 50 cents; 1 lb. bottle, retail, 75 cents.

THE P.P.P. SYRINGE

Is universally considered the most perfect urethral Syringe in the market, because it combines within itself all desirable qualities. It measures but 1½ x 2¾ inches, has a capacity of fully half an ounce, and is made of one piece of soft rubber with conical point. To protect this soft point and to prevent pocket dust from getting into the Syringe, a Hard Rubber cap screws air-tight over it and enables the patient to carry it in his pocket filled with the injection ordered, ready for use when away from home.

For sale by all druggists.

New Remedies and New Combinations.

Pil. Phenacetine et Caffeiæ Citrat., W. H. S. & Co.

Phenacetine-Bayer,	3 grs.
Caffeiæ Citrat.,	1½ grs.

Recommended in cases of Migraine and Nervous Headaches.

Pil. Phenacetine et Salol, 5 grs., W. H. S. & Co.

Phenacetine-Bayer,	2½ grs.
Salol,	2½ grs.

Suggested by Dr. M. F. Price as an anti-rheumatic and analgesic. He says: "I have lately used Phenacetine largely, and have not been disappointed in its action, particularly as an analgesic. I have used it in nearly all cases of pains, especially neuralgic. I have learned to so thoroughly trust it to relieve pain that I often prescribe it without a searching inquiry into the character of the pain. A patient says, 'I have headache,' and I order Phenacetine with confidence, and always with a report of relief."

"It will be observed that in some of these cases I have combined Salol with Phenacetine. I did this on the principle of the well-known effect of Salicylic Acid in Rheumatism, but I rely on the Phenacetine for the relief of the pain, and in this way, perhaps, the cure of the disease causing it."—*Southern California Practitioner.*

Pil. Phencetine et Salol, W. H. S. & Co., ½ strength.

Phenacetine-Bayer,	1¼ grs.
Salol,	1¼ grs.

Pil. Arsenici Sulphidi, 1-100 gr., W. H. S. & Co.

Dr. McLaughlin (Am. Med. Ass'n) finds Sulphide of Arsenic to be tolerated by the stomach better than arsenic in other forms. He gives it in the crude form (Realgar, As 2S2) in granules of 1-100 grain (0.0006 gramme) "ordered from Schieffelin & Co., of New York." In one patient who had suffered from psoriasis more or less for twenty years it was of great service. The eruption was on the arms, back, head, and forehead; his hands were covered with fissures, which bled when the fingers were extended; the nails were black and roughened. One granule increased to 8 granules, t. i. d., in mouth caused the fissures to heal. The face and hands were practically well. The drug was stopped for one week, when the eruption spread very rapidly. The granules were again given and improvement followed in a few days. The general health improved rapidly. In acne and eczema he has obtained satisfactory results. In every case the patient was unaware that arsenic was being administered.—*Journal Am. Med. Ass'n.*

Tablets Sulfonal et Phenacetine, 15 grs., W. H. S. & Co.

Sulfonal-Bayer,	10 grs.
Phenacetine-Bayer,	5 grs.

Glycones

Contain 95 per cent. Pure Glycerin.

Made in both Adult and Infant Sizes.

FOR THE IMMEDIATE RELIEF OF CONSTIPATION.

Glycones are incomparably superior to the glycerin suppositories on the market, inasmuch as the covering is impervious to moisture, unchangeable and easily removed, preserving the Glycones in all climates. The constitution of the Glycones is so modified as to cause no irritation of the rectum.

The value of Glycones in Constipation is well established, painless and copious stools being promptly produced. The Glycerin acts by lubrication and solution of the indurated feces and by stimulating the bowel, thus providing a certain and agreeable method of emptying the colon at pleasure.

After inserting, the Glycone should be retained as long as possible in order to obtain the best results.

Glycones. These invaluable "peristaltic persuaders" are prepared in a most excellent and improved manner by Messrs. Eli Lilly & Co., of Indianapolis. Their Glycones contain 95 per cent. of glycerin, and a beauty of their construction is the peculiar water-proof covering of each Glycone, which is readily and easily removed. By simply pressing upon or slightly squeezing the Glycone between the fingers it slips out with astonishing ease, leaving the covering between the fingers. A great improvement, as any one will readily recognize who has ever made the effort to divest one of the ordinary Suppositories from its lead foil and tissue-paper envelope.—*Medical Practitioner*, Oct., 1889.

FOR SALE BY ALL DRUGGISTS.

Price, 35c. per box (one doz. Glycones), sent by mail.

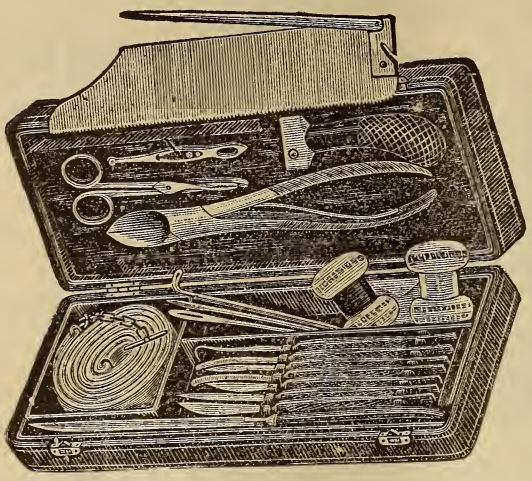
LENTZ'S ASEPTIC COMPACT OPERATING SET, No. 10.



We have from time to time made improvements to this set and are now making a perfect aseptic set, which offers especial facilities for aseptic precautions; the blades are soldered into hollow German-silver handles, nickel-plated, are light so as not to be unwieldy and admit of a firm grasp when operating.

The saw is adjusted to the handle on an entirely new principle, being made to separate easily and to facilitate thorough cleansing.

The handle is entirely of metal and fenestrated to overcome unnecessary weight.

Scissors and Forceps having French locks can be separated, and the slide can be easily removed from Artery and Needle Forceps.

Therefore, no opportunity is offered for the lodgment and development of germs.

The entire set is patterned with especial reference to facility in cleansing.

The instruments can be sterilized by placing them in boiling water, without fear of damaging them. Wood or rubber handles will not admit of this procedure. For price, see case A.

The following instruments are put up in either a fine Mahogany or Morocco case, with nickel trimmings, lined with velvet, and has an extra space for Trephine with handle, and Elevator if desired.

One Amputating Knife (6 in. blade); One Finger Knife; One Hernia Knife; One Sharp Curved Bistoury; Two Scalpels; One Tenotome; One Tenaculum; One Pair Scissors, curved or flat; One Saw (9 in. blade); One Liston's Bone Forceps, with Spring; One Artery and Needle Forceps, improved; One Esmarch's Flat Rubber Tourniquet, with Chain; One Hæmostatic Forceps; One Director, with Aneurism Needle; Two Silver Probes; Silk, Wire, Wax and Needles.

With the Sixteen Instruments Contained in this Case, any Ordinary Operation may be Performed.

SIZE, 11 INCHES LONG, 4 INCHES WIDE, 2 INCHES HIGH.

A.—German Silver aseptic Handles on Knives and Saw,	**$34 00**
B.—Hard Rubber aseptic Handles on Knives and Saw,	**29 00**

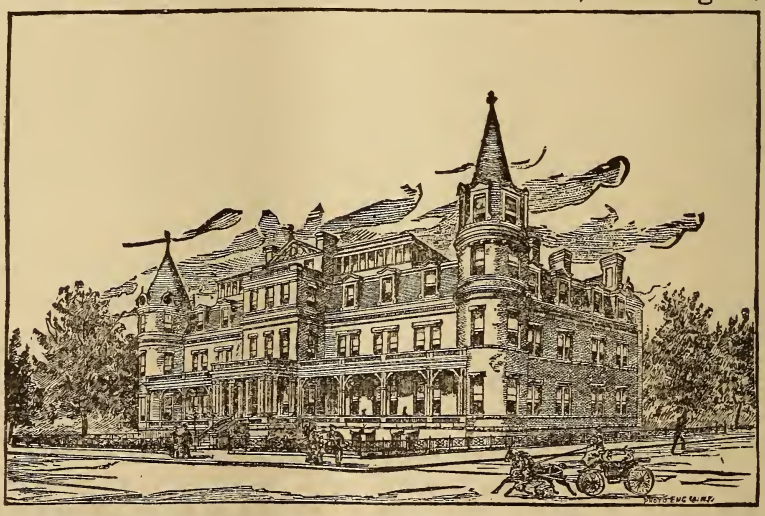
DR. WILLIAM A. HAMMOND'S SANITARIUM,

FOR DISEASES OF THE NERVOUS SYSTEM, Washington, D. C.



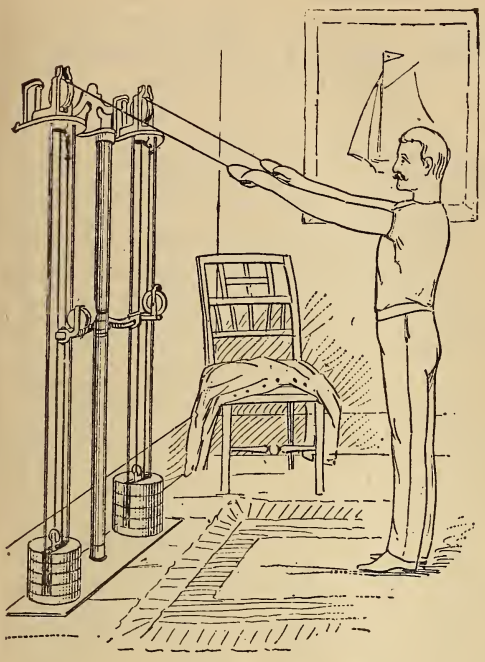
DR. WILLIAM A. HAMMOND announces to the medical profession that he has returned from New York to Washington, D. C., where he has established, in a building especially erected for the purpose, a *Sanitarium* for the treatment of mild and curable cases of mental derangement, diseases of the nervous system generally, cases of the morphia and chloral habits, and such other affections as may properly be treated by the remedial agencies under his control.

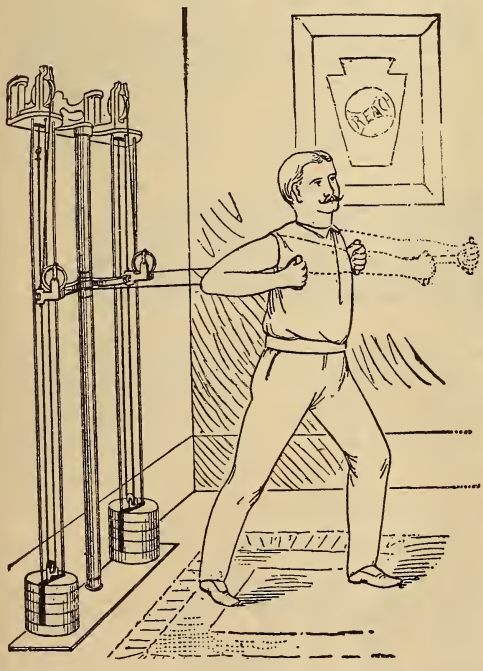
The *Sanitarium* is situated on Columbia Heights, at the corner of Fourteenth Street and Sheridan Avenue. The position is the highest in the immediate vicinity of Washington, the soil is dry, and all the surroundings are free from noxious influences. Electricity in all its forms, baths, douches, massage, inhalations, nursing, etc., are provided as may be required by patients, in addition to such other medical treatment as may be deemed advisable.

A large *Solarium* for sun-baths and exercise in cold or inclement weather and heated with steam in winter, is constructed on the top of the main building.

The *Sanitarium* has now been in successful operation since the 7th of January, 1889.

For further information Dr. Hammond can be addressed at The Sanitarium, Fourteenth Street and Sheridan Avenue, Washington, D. C.





A. G. SPALDING & BROS.'

Gymnasium Department.

From this time henceforth the **Gymnasium** in all its important details will be a department in our business to which we shall devote especial attention.

With the addition to our own valuable patents, those of the **A. J. Reach Company,** of Philadelphia, recently purchased by us, enables us to claim the most **extensive department** of **Gymnasium Appliances in the world.**

We have been encouraged in this **important** movement by the constantly increasing demand from **Colleges, Seminaries,** and other **Educational** Institutions for Gymnasium Supplies, and henceforth we shall devote special attention to furnishing **plans, specifications,** and **estimates** to such and for **private residences** as well, and solicit correspondence with all contemplating the introduction of gymnastics for any purpose.

The Peerless Pulley Weight, illustration of which appears on this page, is a most perfect appliance for the development of the **chest** and **arms,** adjustable to the height of *any* person, and in weight from five to thirty pounds. For **man or woman** this is the peer of any method yet devised, especially for home use. Realizing the attention the **medical profession** and the **teacher,** are now giving to **healthful** exercise in **schools,** we solicit also their correspondence, and any orders, or business prceeding from such, will be gratefully received, and entitled to our best rates of discount, and will receive prompt and careful attention.

Visitors to our different establishments at **Chicago, New York,** and **Philadelphia** will always be welcome and politely served by the many efficient salesmen constantly in attendance.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE**, is prepared from the three Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the three Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THÉ FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

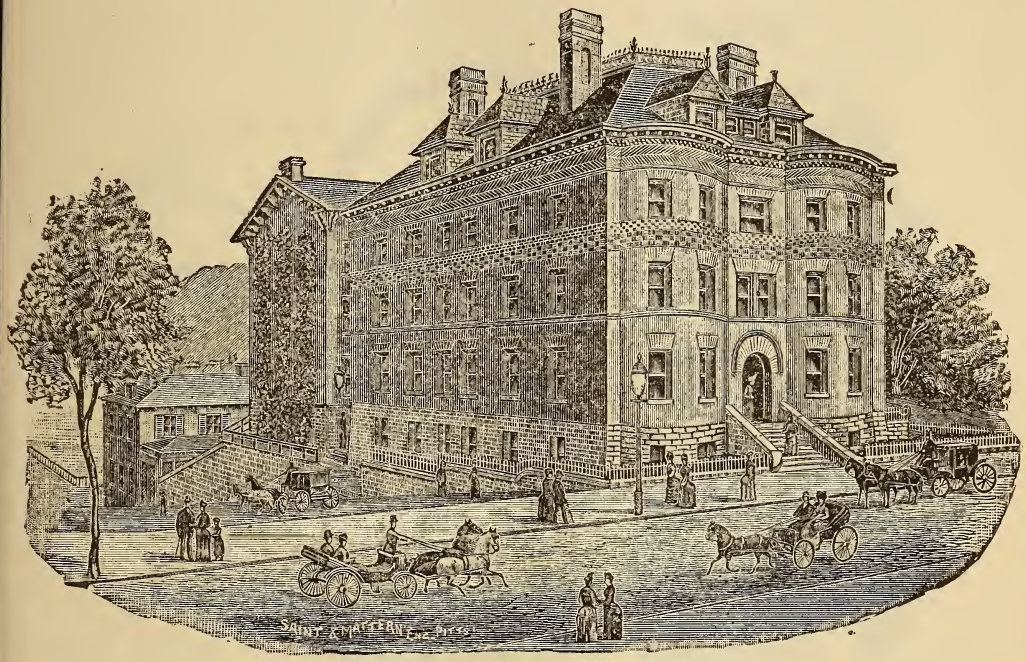
DR. R. S. SUTTON'S

Sanatorium for Diseases of Women.



Eighth Year Opens September 1, 1890.

ALLEGHENY CITY, PA.

This Institution is located on high ground, and overlooks the Allegheny, Monongahela and Ohio rivers; it commands a view of the city of Pittsburgh, and its picturesque surroundings. The building is large and beautiful, it is provided with every modern convenience, the halls are heated by steam, the rooms are commodious, well lighted and ventilated, and heated by open grates. The house is provided with a private parlor and reading-room for patients. The dining-room is large, handsomely finished, and furnished with small tables, securing privacy at meals for those who do not care to have meals served in their own rooms. Patients can be as secluded, should they desire it, as in a well appointed hotel. Each patient is examined by Dr. Sutton, and receives his daily personal attention, while Dr. J. H. Williamson, a physician of ample hospital experience, resides in the Institution, and has, under Dr. Sutton, the immediate care of the patients. The Institution accommodates 25 patients, and is equal in comfort to the best hotels.

Electricity, baths, douches, massage, local treatment, general medication and surgical operations are resorted to according to the requirements of each patient.

For further information address the Matron

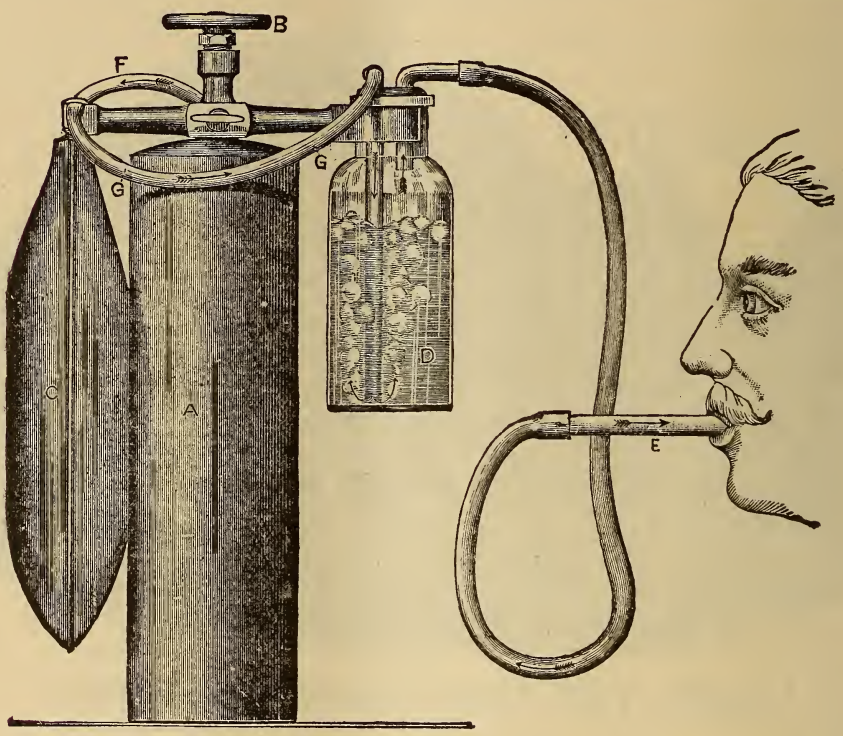
MISS KENNEDY,

170 Ridge Ave., Allegheny, Pa.

INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request:

Sulphur Lotum, U. S. P. . . . . grs. v.
Potass. Bitart., pur. . . . . grs. xv in each tablet.

Put up in metal screw-cap glass jars, containing 35 tablets each. Also in 1 lb. bottles.

A sample of any of these preparations will be mailed to physicians free of charge, on application.

FOR SALE BY THE RETAIL DRUG TRADE GENERALLY.

FRENCH, RICHARDS & CO., Philadelphia, Pa.

GASTRIC DERANGEMENTS.

HORSFORD'S ACID PHOSPHATE.

Unlike all other forms of phosphorus in combination, such as dilute phosphoric acid, glacial phosphoric acid, neutral phosphate of lime, hypophosphites, etc., the phosphates in this product are in solution, and readily assimilative by the system, and it not only causes no trouble with the digestive organs, but promotes in a marked degree their healthful action.

In certain forms of dyspepsia it acts as a specific.

Dr. H. R. MERVILLE, Milwaukee, Wis., says: "I regard it as valuable in the treatment of gastric derangements affecting digestion."

Send for descriptive circular. Physicians who wish to test it will be furnished a bottle on application, without expense, except express charges.

Prepared under the direction of Prof. E. N. HORSFORD, by the

Rumford Chemical Works, Providence, R. I.

Beware of Substitutes and Imitations.

CAUTION:—Be sure the word "HORSFORD'S" is PRINTED on the label. All others are spurious. NEVER SOLD IN BULK.

" Columbo,	½ "
" Phosphorus, C. P.,	1-300 gr.
Aromatics,	2 minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

I. O. WOODRUFF & CO.,

Manufacturers of Physicians' Specialties,

"THIS IS AN AGE OF APOLLINARIS WATER."
—WALTER BESANT.

Apollinaris

"THE QUEEN OF TABLE WATERS."

The filling at the Apollinaris Spring (Rhenish Prussia), amounted to

11,894,000 BOTTLES IN **1887,**
12,720,000 BOTTLES IN **1888** AND
15,822,000 BOTTLES IN **1889.**

"The annual consumption of this favorite beverage affords a striking proof of the widespread demand which exists for table water of absolute purity, and it is satisfactory to find that, wherever one travels, in either hemisphere, it is to be met with; it is ubiquitous, and should be known as the cosmopolitan table water. 'Quod ab omnibus, quod ubique.'"—BRITISH MEDICAL JOURNAL.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

E. FOUGERA & CO., 30 North William St., New York.

Sole Agents for the above Preparations.

GOUDRON DE BLOUNT

PREPARED FROM THE GENUINE CAROLINA TAR.

DOSE.—One fluid drachm four or more times a day (as indicated), either full strength, diluted, or, in combination.

INDICATIONS.—Chronic and acute affections of the Air Passages, Coughs, Colds, Bronchitis, Asthma and Consumption.

WILLIAM MURRELL, M.D., F.R.C.P.,

Lecturer on Pharmacology and Therapeutics at the Westminster Hospital; Examiner in Materia Medica to the Royal College of Physicians of London; Fellow of the Medico-Chirurgical College of Philadelphia,

Says:—"I have used with success 'Goudron de Blount.' The results have been good, and the preparation is popular with patients."

Clinical Notes sent on Application. ST. LOUIS, MO.

REASONS FOR SPECIFYING FAIRCHILD'S PEPSIN.

It is the most active, gives the greatest value for the price asked.

One grain will digest more albumen than will a grain of any other pepsin made. We do not care by whose test, what the proportions of albumen, water, and acid, only let the conditions be the same for all.

It is positively guaranteed to be permanent. It will not get soft or sticky, or deteriorate in value, because it is not a peptone. It is free from all the well-known characteristics of peptone. It is not made by a patented or pirated process.

If you prescribe pepsin in scale or powder, and it becomes sticky, you may be sure that it is not Fairchild's. Investigate the matter, place the blame where it belongs.

There are pepsins "made to sell" under the title of scales—products which are inferior and dissimilar to Fairchild's pepsin in scales. They are peptones made by a patented process and sold under cover of a title first and properly used only by Fairchilds to describe their original, true pepsin in the form of scales.

The druggist is told "they are just as good as Fairchild's. If Fairchild's is not specified, put in mine." But claims and pretensions, however colossal, cannot make peptones permanent.

There is no soluble or peptone pepsin equal in activity to Fairchild's, none which will keep in all weathers and all conditions as Fairchild's will.

FAIRCHILD BROS. & FOSTER, NEW YORK.

ALETRIS CORDIAL

UTERINE TONIC AND RESTORATIVE.

Prepared from the Aletris Farinosa or True Unicorn and Aromatics.

INDICATIONS.

Amenorrhea, Dysmenorrhea, Leucorrhea, Prolapsus Uteri, Sterility, to Prevent Miscarriage, Etc.

DOSE:—ONE TEASPOONFUL THREE OR FOUR TIMES A DAY.

UNRIVALED AS A UTERINE TONIC IN IRREGULAR, PAINFUL, SUPPRESSED AND EXCESSIVE MENSTRUATION.

It Restores Normal Action to the Uterus, and Imparts Vigor to the Entire Uterine System.

☞Where women have miscarried during previous pregnancies, or in any case where miscarriage is feared, the ALETRIS CORDIAL is indicated, and should be continuously administered during entire gestation.

CHAS. CLAY, M. R. C. S., Manor House, Dewsbury, England, says:—I find Aletris Cordial (Rio) is of great service in threatened miscarriage.

FRANCIS E. CANE, L. R. C. S., &c., Leeds, England, says:—I have tried the Aletris Cordial (Rio) in two cases of long standing dysmenorrhea, with excellent results. One of these patients has spent a week in bed every month for two years. After all the usual remedies, I put her on Aletris Cordial, and for the last two periods she has been out and about all the time.

L. M. WATSON, M. D., Delhi, Ills., says:—I have used Aletris Cordial (Rio) in cases of dysmenorrhea. suppressed menses and threatened miscarriage, and also, combined with Celerina, as a tonic after confinement, with the happiest results, and now I am using it on a case of leucorrhea, with injections of S. H. Kennedy's Extract of Pinus Canadensis, and it is acting like a charm.

P. H. OWEN, M. D., Morganville, Ala., says:—I have prescribed Aletris Cordial (Rio) in several cases with the most satisfactory results, and regard it as the best uterine tonic I have met with in a professional experience of over twenty-five years. In cases of threatened miscarriage it acts like a charm. Would recommend its continuous administration in all cases when there is any indication of miscarriage.

Dr. W. BERTHELOT, Santander, Spain, says:—I have tried the Aletris Cordial (Rio), and it has seemed to me to be useful, especially in cases of dysmenorrhea.

Dr. RASQUINET, Jupile, near Liege, Belgium, says:—I tried Aletris Cordial (Rio) in the case of a woman who had had several miscarriages at the end of five months, and who is now again pregnant, having reached the seventh month; thanks to Aletris Cordial.

R. REECE, M. R. C. S., Walton-on-Thames, England, says:—Aletris Cordial (Rio) in painful menstruation is most valuable. A wife of a minister suffered much, and had had three miscarriages. I prescribed Aletris Cordial. She had for the first time, gone her full time, and was safely confined with a male child.

J. T. COLLIER, M. D., Brooks, Me., says:—I have used your Aletris Cordial (Rio) in cases of females at the menopause. Consider it one of the finest remedies for these cases.

Dr. GORDILLON, St. Amand, France, says: I have tried the Aletris Cordial (Rio) in a case of dysmenorrhea. The result I obtained from the use of your preparation was excellent, better than I had obtained in the same patient by prescribing the usual remedies employed in such cases.

W. F. TOOMBS, M. D., Morrillton, Ark., says:—I have used a great deal of your Aletris Cordial (Rio) and I find it all you claim for it in amenorrhea, dysmenorrhea, metritis, leucorrhea; I don't think it has an equal. I have used it in two cases of threatened miscarriage and the trouble was obviated. For a general Uterine Tonic I know of nothing superior.

R. D. PATTERSON, L. R. C. S. &c., Medical Officer, Caledon Dispensary, Co. Tyrone, Ireland, says:—I have very great pleasure in testifying to the very high opinion I hold of Aletris Cordial (Rio) in threatened miscarriage.

A CASE WITH A LESSON IN IT.

We have frequently referred to the necessity of keeping the pregnant woman supplied with those chemical substances which she must give to the child in the formation of its little frame, and the dire effects which may result from a deficiency of those substances. The headaches, neuralgias, spinal tenderness, and some of the many disorders of digestion, and even mental failure, may be all prevented or relieved by supplying to the mother the chemical food her system demands.

We have noticed a few cases where the most serious results have occurred to the mother by such a deficiency, one of which is well worth relating. Mrs. M., aged 30, pregnant with her third child, suffered from the second to the fifth month of her pregnant term with gradually failing strength and health, and nervous irritability. She was very restless nights for three or four days, the peculiar restlessness of complete nervous exhaustion, and was irrational for more than a week.

At this time I advised that she have a teaspoonful of Murdock's Liquid Food every hour in milk, and a little wine every four hours. The third night she had fifteen drops of hydrobromic acid dil. every three or four hours, which was continued for a week. The liquid food after a week every two hours, and all other medicines were discontinued. Her bowels were moved with a mild laxative at first, and afterward became regular. Her tongue cleaned quickly and her skin assumed a more natural appearance.

At this writing, less than three weeks from our first visit, the patient is able to sit up an hour at a time, is quite rational and cheerful, has a good appetite, the bowels are quite regular, there is no headache, and but little spinal tenderness. She sleeps reasonably well if fed frequently. She is allowed to suit her taste in her diet. The child is quite active, and the mother is progressing so nicely that it is hoped that she will pass safely through her confinement, which is nearly at hand. She will be kept on the liquid food and the phosphates until her confinement after which, the condition will suggest the treatment. This is the most marked case of a starved nervous system we have ever seen, and the benefit derived from the treatment proves the theory as to the cause of the trouble.

Apropos with the above, comes the question of the selection of nutritious foods for those many cases which demand strong and immediate nourishment. The food used in the above case has produced marvelous results for us in some of those extreme cases in which we have used it.

In one case of nervous exhaustion the insomnia was absolutely painful. When the exhaustion forced the patient to sleep there was an immediate sense of falling or approaching death, or there were hallucinations which were appalling, rendering the nights unbearable. One teaspoonful of Murdock's Liquid Food so nourished the system the first night it was given that the patient sank into a quiet, refreshing sleep which lasted, with a single awakening, until morning, and the improvement the patient obtained was most striking.

One case of mitral regurgitation with leucocythemia and nervous exhaustion improved more rapidly on this food than on all other measures combined. In cases of nervous exhaustion and brain tire, its effects are most marked, as we have experienced many times in the past five years in the frequent personal use of the agent. It contains the principles of pure, healthy blood and nerve tissue ready for immediate assimilation. Fourteen per cent. of the entire quantity is uncoagulated albumen, as we have demonstrated by actual analysis.

We have tided babies over critical periods often with a few drops in its usual diet. We have given it to dipsomaniacs with or without non-alcoholic stimulants with superb results. The sole objection our patients have to it is its odor. Its taste is not disagreeable; it has the odor and appearance of blood. All objections are soon forgotten, however, in the results of its action upon the nutrition of the system, and the patient soon learns to like it, and often craves for it, drinking it from the bottle or a glass readily, like any beverage. It ought to be the food par-excellence for rapid appropriation in all conditions of exhaustion.

P. S.—Phosphates act well with the Liquid Food.

Editorial of the Chicago *Medical Times*, June, 1890.

In 97% of all cases where mother's milk is scanty or poor a copious flow of rich milk will be caused in 3 days by giving the mother "nutrolactis". Using this remedy mothers become stronger, infants thrive notably. Try it Doctor

LIQUOR SANTAL FLAV.

CUM

BUCHU ET CUBEBA.

(ORIGINAL FORMULA.)

This elegant preparation has been very successfully used in the treatment of long-standing Gonorrhœa and chronic Gleet.

If given in the early stages of Gonorrhœa, it will usually arrest the progress of the disease.

It is especially effective in all inflammations of genito-urinary mucous membranes.

It is perfectly miscible in water. Dose, f℥i to f℥ij, three times a day in water or milk. When prescribing, please specify Liq. Santal Flav. cum Buchu et Cubeba (Ogden's).

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1890—91.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. T. M. T. McKENNAN.

Business correspondence should be addressed to

PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

Woman's Medical College

OF BALTIMORE,

S. E. Cor. Druid Hill Ave. and Hoffman Street.

THE NINTH REGULAR SESSION WILL BEGIN OCTOBER 1ST, 1890, and continue seven months. For further information or catalogue, apply to

RANDOLPH WINSLOW, M. D., Dean,

No. 1 Mount Royal Terrace, Baltimore, Md.

COLLEGE OF PHYSICIANS AND SURGEONS

OF BALTIMORE, Md.

The Preliminary Course will begin September 15, 1890.

The Regular Session will open October 1, 1890, and close April 1, 1891. For catalogue containing full information, write to

Practical individual instruction, Clinical and Demonstrative, to physicians only, during the entire year. Fee for any one branch for six weeks, **$15.00**; General Ticket for twelve Clinical branches, **$100.00**; Tickets good for one Clinic weekly for three months, issued on application. For Announcement, with full particulars of CLINICAL AND LABORATORY COURSES, address

S. SOLIS-COHEN, M. D., Secretary.

MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

WINTER SESSION will begin Wednesday, October 1st, and continue until April 16th. PRELIMINARY SESSION begins September 8th. SPRING TERM, April 20th, 1891.

The curriculum is graded, and a preliminary examination and three Annual Winter Sessions are required. Laboratory instruction in Chemistry, Histology, Pathology, Hygiene, Physiology, with Bedside instruction in Medicine, Surgery and Gynecology, is a part of the regular course.

Fees: Matriculation $5.00. First and second years, each $75.00. Third year $100.00. Fourth year free to those in attendance three sessions; to all others $100.00.

For Announcement or information apply to

E. E. MONTGOMERY, M. D.,

1818 Arch Street, Philadelphia, Pa.

THE JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA.

The 66th Annual Session of the Jefferson Medical College begins October 1st and continues nearly 7 months. Preliminary Lectures will be held from 22d of September.

EACH student is immediately and personally taught in Obstetrics and Gynæcology, Physical Diagnosis, Laryngology, Ophthalmology, Medical Chemistry, Pharmacy, Materia Medica, and Experimental Therapeutics, Histology and Experimental Physiology, Minor Surgery, Bandaging, Operations on the Cadaver, Pathology, Neurology, and Electro-Therapeutics.

Three annual regular sessions are required. Bedside instruction in Medicine, Gynæcology, Surgery and Obstetrics is a part of the third year course. No extra fee.

The **Annual Announcement** will be sent on application to

J. W. HOLLAND, M. D., Dean.

Medical Department, State University of Iowa,
AT IOWA CITY, IOWA.

The next session will begin on September 10th, 1890, and continue until March 11th, 1891.

Attendance upon three courses of lectures, of six months each, is requisite to graduation. Facilities for dissection and clinical study are unsurpassed.

Term Expenses:—Lecture Ticket, $20.00; Demonstrator's Ticket, $10.00; Matriculation Ticket, $5.00 (paid but once); Hospital Ticket, $3.00; Examination Fee (for final examination), $25.00. No charge for dissecting material.

GENUINE BLAUD'S PILLS.

These pills, which have been inserted in the new French Pharmacopœia, have been employed with the greatest success for more than fifty years by most French and foreign physicians, to cure anemia, chlorosis, and all chlorotic affections in which iron is indicated.

Here is the opinion of men most eminent in medical science who have employed them:

"For thirty-five years, in which I have practised medicine, I have recognized the incontestable advantages of BLAUD'S PILLS over all other ferruginous preparations, and I regard them as the best anti-chlorotic."—DR. DOUBLE, *Ex-President of the Academy of Medicine.*

"Of all the ferruginous preparations, which have given good results in the treatment of chlorotic affections, BLAUD'S PILLS appear to us to deserve to hold the first rank."—*Dictionnaire universel de médecine,* Vol. II, p. 99.

These pills, prepared according to the genuine formule of the originator, by his nephew, Aug. Blaud, Pharmacist of the Faculty of Paris, are sold only in bottles of 200 pills and half bottles of 100 pills, at a cost of 5 and 3 francs ($1.00, and seventy-five cents), and never in smaller quantities. *See that his name is stamped on each pill.* **PARIS, 8 RUE PAYENNE, and at every Pharmacy.** (Beware of imitations.)

BLAUD

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y.

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

"What a boon it would be to the Medical Profession if some reliable Chemist would bring out an Extract of Malt in combination with a well-digested or peptonized Beef, giving us the elements of Beef and the stimulating and nutritious portions of Ale."—J. MILNER FOTHERGILL, M.D.

Ale & Beef

"PEPTONIZED"

(EXTRACT:—BOVIS CUM MALTO.)

's the identical combination suggested by the late eminent Fothergill.

EACH BOTTLE REPRESENTS 1-4 POUND
OF LEAN BEEF THOROUGHLY PEPTONIZED.

It is the only Mild Stimulant combined with a Perfect Food known. It is very palatable, aids digestion, is retained by the most delicate stomach, and the purity of its ingredients is guaranteed.

THE "PEPTONIZED" BEEF

is manufactured by Prof. Preston B. Rose, of Chicago, late of the faculty of the University of Michigan.

THE ALE USED
IS THE PUREST AND BEST MADE IN AMERICA

Especially brewed for this purpose, and guaranteed to be equal to the best imported ales, as only the best Canada Malt and the choicest new hops are used in its manufacture.

IT IS A REAL FOOD; NOT A MERE STIMULANT,

as it contains all the albumen and fibrin of the beef as well as the nutritive qualities of the malted barley.

It is most useful during the period of Gestation, in allaying all vomiting, and invaluable to Nursing Mothers; also in Typhoid Fever and Dysentery.

Prof. G. A. Liebig says: "A careful chemical examination of the Peptonized Ale and Beef shows a much larger per cent. of nitrogenous blood and muscle-making matter over all other malt extracts, and that it is also rich in Diastase, giving it the power to digest Starch Foods."

PREPARED BY

The Ale and Beef Company,

DAYTON, OHIO, U. S. A.

Two full-sized bottles will be sent FREE to any physician who will pay express charges.
Please mention this journal.

The Model Ledger

enables a physician to make out his bills with great ease. Beside this, it tells at a glance just how much he has earned in any quarter; how much he has received; and how much is still due him. These are all good things for a doctor to know.

GLYCOZONE

Is used as an internal remedy, or for local dressings. It is absolutely harmless; and Ozone is its healing agent.

GLYCOZONE, by its wonderful antiseptic and healing properties, not only prevents the fermentation of the food in the stomach, but it quickly cures the inflammation or irritation of the mucous membrane. It is a specific for disorders of the stomach: **Dyspepsia, Catarrh of the Stomach, or Gastritis, Ulcer of the Stomach, Heart-Burn.** Sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing CHAS. MARCHAND'S label and signature.

Prepared only by Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

A book containing full explanations concerning the therapeutical applications of GLYCOZONE, with opinions of the profession, will be mailed to physicians free of charge on application.

Doctor:

How is that case of scrofula getting along? About the same old way as it has for years, is it not?

You see by this time that the alteratives and general tonics give but temporary benefit. Sometimes, in fact, they irritate and aggravate the case.

Did you ever think what is the real pathology of scrofula?

It is deficiency or degeneration of the tissue walls. This allows extravasations of blood, and diapedesis of white corpuscles, forming eruptions and suppuration. It is not "bad blood," but bad tissues.

Notice that rickety building over there. It is crumbling while those near it, much older, are still strong. What is the matter? Bad bricks and mortar in its walls. It can be stayed awhile with props, but soon the radical change must come of tearing it down and building it over with good material.

Now, Doctor, your scrofulous patient is in the same condition, with this difference: Nature is constantly removing the old material in his tissue walls, and replacing it with new. In seven years, without any cessation in his existence, he will be composed of entirely new material. This gives you a golden opportunity to put in some extra good material.

What shall it be?

Shall it be iron, quinine, strychnine, arsenic and manganese? No. They only prove to be irritants. The only remedy is the hypophosphites of lime and soda—the true reconstructives of the tissues. By using them faithfully and constantly you will gain gradual improvement at once and permanent cure in a few years.

You see the philosophy of it, don't you?

The only chemically pure preparation of these tissue foods is McArthur's Compound Syrup of the Hypophosphites of Lime and Soda. All others contain, in addition, the irritant "tonics," so delusive in their results. Be sure that your patients are served with none other than McArthur's. You can add to it in the prescription any other remedy specially indicated at special times.

Other diseases particularly requiring this remedy are Tuberculosis (twin brother of Scrofula), Rachitis, Chronic Cough, Chronic Bronchitis and Throat Affections, Chronic Alcoholism, Impotence, Nervousness, General Debility, Brain Exhaustion, Loss of Memory, Chronic or Wasting Diarrhœa, Suppurating Discharges and Sores, Uterine Fibroids, and all diseases characterized by waste or faulty nutrition.

Write your prescription thus:

℞ Syr: Hypophos: Comp: McArthur: One Bottle.

As it is made *only for Physicians*, there are no printed wrappers or other advertisements on the bottle.

Our pamphlet on the "Curability and Treatment of Consumption" sent free to physicians upon application. We will send one bottle of McArthur's Syrup free to any physician who will pay the express charges.

THE P.P.P. SYRINGE

Is universally considered the most perfect urethral Syringe in the market, because it combines within itself all desirable qualities. It measures but 1½ x 2¾ inches, has a capacity of fully half an ounce, and is made of one piece of soft rubber with conical point. To protect this soft point and to prevent pocket dust from getting into the Syringe, a Hard Rubber cap screws air-tight over it and enables the patient to carry it in his pocket filled with the injection ordered, ready for use when away from home.

For sale by all druggists.

ARISTOL.

ARISTOL, a combination of iodine and thymol, manufactured by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, Germany, is a valuable, inodorous and non-toxic antiseptic remedy, said to be superior to Iodoform, Iodole and Sozo-Iodole.

ARISTOL is insoluble in water and glycerine, and very sparingly in alcohol, but is very easily soluble in ether and chloroform. The ether solution is precipitated by the addition of alcohol. ARISTOL is very freely soluble in fatty oils. The solution must be made in the cold, by stirring, as the use of heat causes a decomposition. For the same reason it is necessary to protect the body from light and keep it in opaque bottles. It very readily adheres to the skin, and can thus be used as a powder strewn over wounds and burns.

In cases of mycosis it also acts well, and more quickly than any other known remedy, and does not cause irritation, like so many drugs.

The effective use of ARISTOL in psoriasis is of great interest, as our Materia Medica has hitherto supplied us with no non-poisonous drug, save only chrysarobin, the use of which is associated with a deep skin coloration and conjunctivitis—drawbacks from which ARISTOL is absolutely free.

In cases of lupus it is said to surpass even the best known remedies.

The value of ARISTOL can scarcely be over-estimated, as we have in it a drug possessing the good properties of Iodoform, but free from its toxic qualities. Its freedom, too, from any suspicious odor will be at once appreciated, both by the physician and his patient.

ARISTOL, prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, is supplied by us in ounces.

SULFONAL-BAYER.

The value of Sulfonal in children's diseases.—DR. WILLIAM C. WILE sent a paper with this title to the American Medical Association, in which he stated that Sulfonal was the ideal hypnotic. It was without the bad effects of opium and the uncertainty of the bromides. It could be given in ten-grain doses. It quieted reflex irritability. It did not constipate nor disturb the stomach. In one case in which a drachm was taken accidentally in ten-grain doses, there was a deep slumber lasting twenty-four hours, slight fever, but a normal pulse and respiration.—*Medical Record*, New York.

DR. HENRY M. FIELD, in a paper presented to the American Medical Association, says:—"Clinically observed, we recognize in Sulfonal a mild calmative, *a slowly, but progressively acting hypnotic;* it has no other action, and its operation is attended by no complications, near or remote. It is therefore a pure hypnotic, and, we submit, it is the only pure hypnotic we possess, up to date."—*New England Medical Monthly.*

Sulfonal-Bayer, prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, is supplied by us in ounces and in the form of Tablets of 5, 10 and 15 grains, put up in bottles of 10 and 100 tablets each.

We also offer Sulfonal-Bayer in the form of our soluble pills, containing 5 grains each.

PHENACETINE-BAYER.

Phenacetine in Insomnia.—DR. F. PEYRE PORCHER, of Charleston, S. C., writes: "I desire to call special attention to the extreme value of Phenacetine as a remedy for insomnia. Given at night in a little water it is tasteless, innocuous, and induces sleep. I am confident, also, after repeated trials, that it is the best and most unobjectionable substitute for morphia. It causes sleep when, of course, pain is in abeyance, unless the pain be more than ordinary, and morphia hypodermically may then be required. The remedy may be repeated and the dose increased to seven or ten grains.

"Suffering from chronic rheumatism of the forearm, I have tested it repeatedly in my own person, and have given it to many who have suffered from insomnia, or inability to sleep from any transient cause, fatigue, nervousness, excitement, etc., in either sex." * * * * *—*Medical Record*, New York.

Phenacetine-Bayer, prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, is supplied by us in ounces and also in the form of our soluble pills and compressed tablets, containing two, four and five grains each. Either form may be obtained of any reputable apothecary.

It gratifies us to be able to announce that PHENACETINE, SULFONAL and SALOL have been incorporated into the new German Pharmacopœia just issued, and have been proposed by the General Medical Council of Great Britain for introduction into the forthcoming Addendum to the British Pharmacopœia. This action confirms and endorses our judgment in introducing these valuable remedies to the medical profession of the United States, and is a natural sequence of the favorable results experienced in their employment, and of the brilliant and conclusive testimony thereof, which had been so freely furnished by the most talented of the profession both in Europe and in the United States.

W. H. Schieffelin & Co.,

170 & 171 WILLIAM STREET,

NEW YORK.

ESTABLISHED 1855.

DRS. STRONG'S SANITARIUM,

SARATOGA SPRINGS, NEW YORK,

Receives persons recommended to it by their home physicians for Treatment, Change, Rest or Recreation, and places them under well-regulated hygienic conditions so helpful in the treatment of chronic invalids or the overtaxed.

For Treatment: In addition to the ordinary remedial agents, it employs Turkish, Russian, Roman, Sulphur, Electro-Thermal, the French Douche (Charcot's), and all Hydropathic Baths; Vacuum Treatment, Swedish Movements Massage, Pneumatic Cabinet, Inhalations of Medicated, Compressed, and Rarefied Air, Electricity in various forms, Thermo-Cautery, Calisthenics, and Saratoga Waters, under the direction of a staff of educated physicians.

For Change: This Institution is located in a phenomenally dry, tonic, and quiet atmosphere, in the lower arc of the Adirondack Zone, and within the "Snow Belt."

For Rest: The Institution offers a well-regulated, quiet home, heated by steam and thoroughly ventilated, with cheering influences and avoiding the depressing atmosphere of invalidism.

For Recreation: To prevent introspection, are household sports at all seasons of the year, and in Winter, tobogganning, elegant sleighing, etc.; in Summer, croquet, lawn-tennis, etc.

Private professional references furnished upon application. Physicians are invited to inspect the Institution at their convenience. A liberal discount to physicians and their families.

For further information, address,

DRS. S. S. & S. E. STRONG.

OTTO FLEMMING,

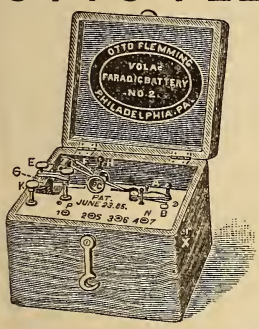
MANUFACTURER OF

Electric Specialties,

FOR USE IN

MEDICINE and SURGERY.

1009 Arch St., Phila., Pa.



I invite the closest scrutiny, analysis, and tests of the qualities of my new Vola-Batteries; my claim being, superior efficiency and regularity in their working capacity by perfect absence of annoyance, resulting from fluid in the cells. Complete apparatus for use in Electro-Gynæcology, with suitable Electrodes, Milliampere Meters, Current Controllers, Cautery Batteries, etc.

DR. MASSEY'S

PRIVATE SANITARIUM

3607 Locust Street

PHILADELPHIA

This institution, in addition to complete arrangements for the treatment of Nervous Diseases by rest, electricity, massage, etc., under comfortable surroundings, is specially equipped for the treatment of cases of Fibroid Tumors and other intractable diseases of the pelvic viscera, by the conservative use of strong electric currents. For particulars, address

DR. G. BETTON MASSEY

1706 Walnut Street, Philadelphia

A Phosphorized Cerebro-Spinant

(FRELIGH'S TONIC).

FORMULA.

Ten minims of the Tonic contain the equivalents (according to the formulæ of the U. S. P., and Dispensatory) **of**

Tinct. Nux Strychnos,	1 minim.
" Ignatia Amara,	1 "
" Cinchona,	4 "
" Matricaria,	1 "
" Gentian,	½ "
" Columbo,	½ "
" Phosphorus, C. P.,	1-300 gr.
Aromatics,	2 minims.

Dose: 5 to 10 drops in 2 tablespoonfuls of water.

INDICATIONS.

Paralysis, Neurasthenia, Sick and Nervous Headache, Dyspepsia, Epilepsy, Locomotor Ataxia, Insomnia, Debility of Old Age, and in the Treatment of Mental and Nervous Diseases.

A BALTIMORE PHYSICIAN, WHOSE DIPLOMA DATES FROM 1825, SAYS:

"Your combination I find vastly more effective than any tonic I have ever used. It furnishes a most powerful evidence of the vastly increased power of medicament by combination and judicious pharmaceutic preparation."

Price, One Dollar per Bottle, containing 100 of the Average 5-Drop Doses.—Physicians' single sample delivered, charges prepaid, on application. That every physician may be his own judge of its value, irrespective of the opinions of others, we make the following

SPECIAL OFFER:

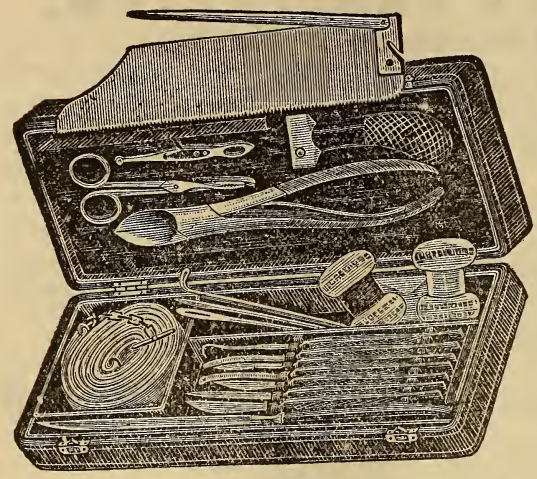
We will send to any physician, delivered, charges prepaid, on receipt of twenty-five cents, and his card or letter-head, half a dozen physicians' samples, sufficient to test it on as many cases for a week to ten days each. The Tonic is kept in stock regularly by all the leading wholesale druggists of the country. As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-lists, etc., address,

I. O. WOODRUFF & CO.,

Manufacturers of Physicians' Specialties,

No. 88 Maiden Lane, New York City.

LENTZ'S ASEPTIC COMPACT OPERATING SET, No. 10.



We have from time to time made improvements to this set and are now making a perfect aseptic set, which offers especial facilities for aseptic precautions; the blades are soldered into hollow German-silver handles, nickel-plated, are light so as not to be unwieldy and admit of a firm grasp when operating.

The saw is adjusted to the handle on an entirely new principle, being made to separate easily and to facilitate thorough cleansing.

The handle is entirely of metal and fenestrated to overcome unnecessary weight.

Scissors and Forceps having French locks can be separated, and the slide can be easily removed from Artery and Needle Forceps.

Therefore, no opportunity is offered for the lodgment and development of germs.

The entire set is patterned with especial reference to facility in cleansing.

The instruments can be sterilized by placing them in boiling water, without fear of damaging them. Wood or rubber handles will not admit of this procedure. For price, see case A.

The following instruments are put up in either a fine Mahogany or Morocco case, with nickel trimmings, lined with velvet, and has an extra space for Trephine with handle, and Elevator if desired.

One Amputating Knife (6 in. blade); One Finger Knife; One Hernia Knife; One Sharp Curved Bistoury; Two Scalpels; One Tenotome; One Tenaculum; One Pair Scissors, curved or flat; One Saw (9 in. blade); One Liston's Bone Forceps, with Spring; One Artery and Needle Forceps, improved; One Esmarch's Flat Rubber Tourniquet, with Chain; One Hæmostatic Forceps; One Director, with Aneurism Needle; Two Silver Probes; Silk, Wire, Wax and Needles.

With the Sixteen Instruments Contained in this Case, any Ordinary Operation may be Performed.

SIZE, 11 INCHES LONG, 4 INCHES WIDE, 2 INCHES HIGH.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE**, is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.

E. FOUGERA & CO., New York,

Sole Agents for the United States for the above Preparations.

An Open Letter to the Medical Profession.

THE INFANT FOOD PROBLEM SOLVED.

NEW YORK, May 1, 1890.

The Annual of the Universal Medical Sciences for 1889 says: "A perfect Infant Food is still a desideratum; such a food will probably be evolved in the mind of some manufacturer who understands the physiology of infantile digestion and the chemistry of milk. A substitute for human milk to approximate the latter closely should be made entirely from cow's milk, without the addition of any ingredient not derived from milk."

"But not alone do we demand that these Milk Foods contain the equivalent of the solids in human milk, and especially of the albuminoids derived from milk, but that the latter be gathered with the utmost care from properly fed animals, transported with the least possible jolting to the factory, maintained during its transit at a low temperature, then transferred to an apparatus for sterilization, and immediately after the latter has been accomplished reduced to the dry state, in order to prevent the formation of those organisms which Loeffer, Pasteur, and Lester have found to develop in fluid milk after boiling under an alkaline reaction. If such a preparation be put into air-tight and sterilized jars, all will have been accomplished that can be done to render the food sterile, and thus fulfil the chief indications in the prevention of the most serious gastro-intestinal derangements."

"Such a food, too, would have the advantage of being easily and rapidly prepared by addition of sterilized water, affording an altogether sterilized food."

To the *Medical Profession* at large we submit for examination and trial the perfected Milk Food known as LACTO-PREPARATA. We claim that LACTO-PREPARATA is an *ideal Infant Food*, and that it fulfils the above requirements in every particular, except the partial substitution of cocoa-butter for unstable milk-fat. This substitution was made by advice of Prof. Attfield, London, who made extensive tests of its food value and digestibility in the London Hospitals for Infants.

LACTO-PREPARATA is made from cow's milk evaporated in vacuo a few hours after it leaves the udder. In order to have the product correspond in composition with breast-milk, sufficient milk-sugar is added to bring up the carbohydrates and reduce the albuminoids to a proper proportion (17 per cent.). The casein is partially pre-digested (30 per cent.), and the remaining portion is rendered like human milk in character and digestibility. The ingredients are perfectly sterilized and placed in hermetically sealed cans; the powdering, bolting, and canning are done in an air-tight room, all air entering and leaving this room is forced by a blower through heavy layers of cotton. LACTO-PREPARATA is adapted more especially to infants from birth to six months of age; *and by the addition of water alone represents almost perfectly human milk in taste, composition, and digestibility.*

Another product of our laboratory which has been before the profession for a number of years is CARNRICK'S SOLUBLE FOOD, which, as now prepared and perfected, contains 37½ per cent. of the solid constituents of milk, 37½ per cent. of wheat with the starch converted into dextrine and soluble starch, and 25 per cent. additional milk-sugar. For infants over six months of age it is perfect in every respect; for infants younger than this, LACTO-PREPARATA is more suitable, although *Soluble Food* has also been used largely from birth with the most satisfactory results.

Samples will be sent prepaid, also pamphlet giving detailed description.

REED & CARNRICK, NEW YORK.

"Medical Press and Circular,"

BY

EDWARD WARREN-BEY, M. D., C. M., LL. D.,

Chevalier of the Legion of Honour.

To those familiar with the use of BROMIDIA, no argument is necessary, for it speaks for itself, by fulfilling the indications for which it is administered with a certainty, efficiency, and harmlessness which elicit at once the wonder of the patient and the delight of the prescriber, and give to the profession the assurance of possessing one remedy at least which approximates so near to infallibility of action as to justify the title of *specific.*

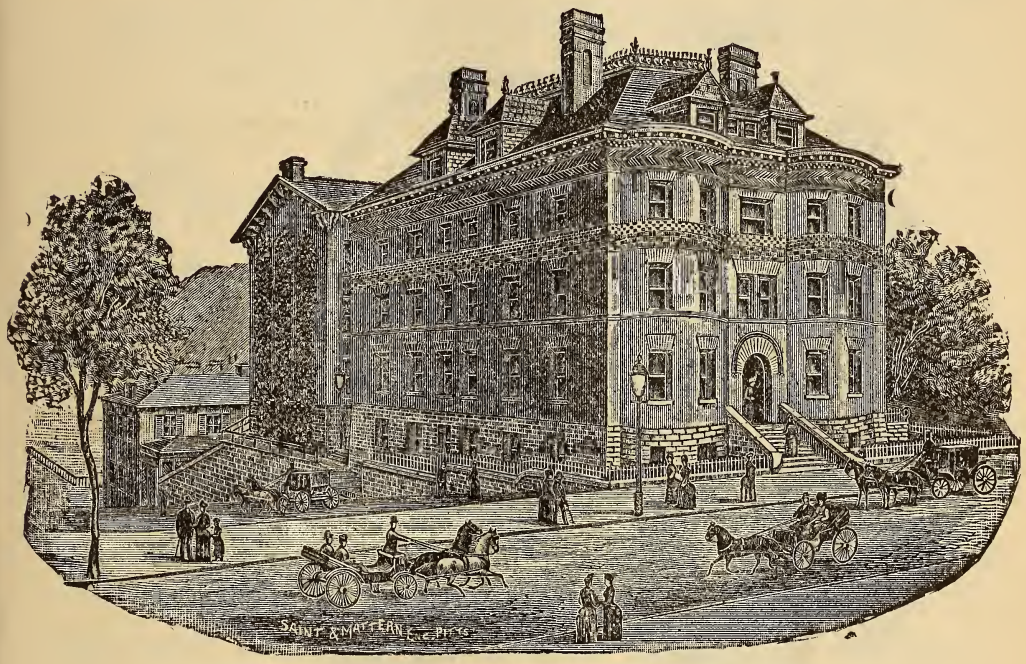
DR. R. S. SUTTON'S

Sanatorium for Diseases of Women.



Eighth Year Opens September 1, 1890.

ALLEGHENY CITY, PA.

This Institution is located on high ground, and overlooks the Allegheny, Monongahela and Ohio rivers; it commands a view of the city of Pittsburgh, and its picturesque surroundings. The building is large and beautiful, it is provided with every modern convenience, the halls are heated by steam, the rooms are commodious, well lighted and ventilated, and heated by open grates. The house is provided with a private parlor and reading-room for patients. The dining-room is large, handsomely finished, and furnished with small tables, securing privacy at meals for those who do not care to have meals served in their own rooms. Patients can be as secluded, should they desire it, as in a well appointed hotel. Each patient is examined by Dr. Sutton, and receives his daily personal attention, while Dr. J. H. Williamson, a physician of ample hospital experience, resides in the Institution, and has, under Dr. Sutton, the immediate care of the patients. The Institution accommodates 25 patients, and is equal in comfort to the best hotels.

Electricity, baths, douches, massage, local treatment, general medication and surgical operations are resorted to according to the requirements of each patient.

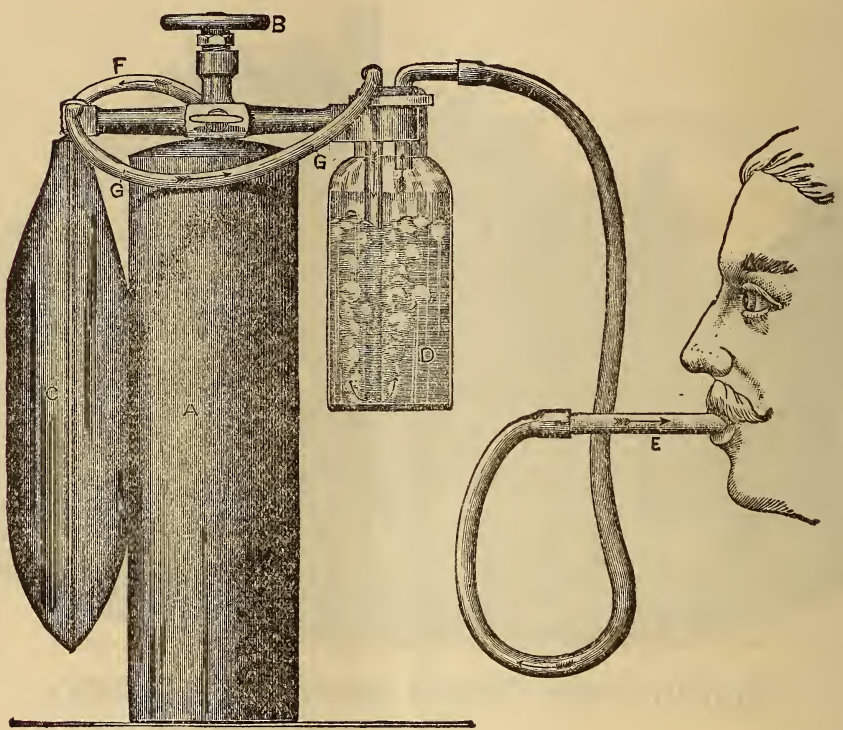
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.
LAMBERT'S
LITHIATED HYDRANGEA
KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request.

LAMBERT PHARMACAL CO., ST. LOUIS, MO.

FRENCH'S
COMPRESSED ANTISEPTIC PASTILLES.
(Dr. CARL SIELER'S FORMULÆ.)

FOR MAKING ANTISEPTIC SPRAYS, NASAL WASH, MOUTH WASH, Etc.

One tablet dissolved in four tablespoonfuls of warm water makes a solution which can be used as a spray or wash.

Supplied in bottles of 50, 100 and 1 lb.

COMPRESSED ANTISEPTIC TABLETS.
(FOR EXTERNAL USE.)

Each tablet contains:

7.3 grains . . . . . Hydrarg. Bichlor.
7.7 grains . . . . . Ammon. Clor.

One tablet dissolved in one pint of water will make a 1 to 1,000 solution, containing one part of Corrosive Sublimate in 1,000 parts of water.

Supplied in screw-cap bottles, containing 25 and 100 tablets each, and pounds.

FRENCH'S
COMPRESSED SULPHUR and CREAM OF TARTAR TABLETS.

An alterative and mild laxative for children and invalids. They are pleasantly flavored and sweetened, and form an agreeable method of medication.

FORMULA:

Sulphur Lotum, U. S. P. . . . . grs. v.
Potass. Bitart., pur. . . . . grs. xv in each tablet.

Put up in metal screw-cap glass jars, containing 35 tablets each. Also in 1 lb. bottles.

A sample of any of these preparations will be mailed to physicians free of charge, on application.

FOR SALE BY THE RETAIL DRUG TRADE GENERALLY.

FRENCH, RICHARDS & CO., Philadelphia, Pa.

Champagne ANALYZED

Of Interest to all Medical Practitioners.

WHAT IS SAID BY

THOMAS KING CHAMBERS, M.D., F.R.C.P.
R. OGDEN DOREMUS, M.D.
F. W. PAVY, M.D., F.R.S.

"Champagne, with a minimum of alcohol, is by far the wholesomest, and possesses remarkable exhilarating power."—THOMAS KING CHAMBERS, M.D., F.R.C.P.

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co.'s Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it not only for its purity but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M.D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

"Champagne, while only possessing the alcoholic strength of natural wines, is useful for exciting the flagging powers in case of exhaustion."—F. W. PAVY, M.D., F.R.S., *Lecturer on Physiology at Guy's Hospital, London.*

The remarkable vintage of 1884 of **G. H. MUMM & CO.'S EXTRA DRY CHAMPAGNE,** the finest for a number of years.
Pronounced by connoisseurs unsurpassed for excellence and bouquet.

FRED'K DE BARY & CO., New York,

SOLE AGENTS IN THE UNITED STATES AND CANADA.

REASONS FOR SPECIFYING FAIRCHILD'S PEPSIN.

It is the most active, gives the greatest value for the price asked.

One grain will digest more albumen than will a grain of any other pepsin made. We do not care by whose test, what the proportions of albumen, water, and acid, only let the conditions be the same for all.

It is positively guaranteed to be permanent. It will not get soft or sticky, or deteriorate in value, because it is not a peptone. It is free from all the well-known characteristics of peptone. It is not made by a patented or pirated process.

If you prescribe pepsin in scale or powder, and it becomes sticky, you may be sure that it is not Fairchild's. Investigate the matter, place the blame where it belongs.

There are pepsins "made to sell" under the title of scales—products which are inferior and dissimilar to Fairchild's pepsin in scales. They are peptones made by a patented process and sold under cover of a title first and properly used only by Fairchilds to describe their original, true pepsin in the form of scales.

The druggist is told "they are just as good as Fairchild's. If Fairchild's is not specified, put in mine." But claims and pretensions, however colossal, cannot make peptones permanent.

There is no soluble or peptone pepsin equal in activity to Fairchild's, none which will keep in all weathers and all conditions as Fairchild's will.

FAIRCHILD BROS. & FOSTER, NEW YORK.

"THIS IS AN AGE OF APOLLINARIS WATER."
—WALTER BESANT.

Apollinaris

"THE QUEEN OF TABLE WATERS."

The filling at the Apollinaris Spring (Rhenish Prussia), amounted to

11,894,000 BOTTLES IN **1887,**
12,720,000 BOTTLES IN **1888** AND
15,822,000 BOTTLES IN **1889.**

"The annual consumption of this favorite beverage affords a striking proof of the widespread demand which exists for table water of absolute purity, and it is satisfactory to find that, wherever one travels, in either hemisphere, it is to be met with; it is ubiquitous, and should be known as the cosmopolitan table water. 'Quod ab omnibus, quod ubique.'"—BRITISH MEDICAL JOURNAL.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonary Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

E. FOUGERA & CO., 30 North William St., New York.

Sole Agents for the above Preparations.

GARDNER'S

SYRUP OF HYDRIODIC ACID,

Introduced in 1878 by R. W. GARDNER.

The Reputation which Hydriodic Acid has Attained During the past Eleven Years was Won by this Preparation.

Numerous Imitations prepared differently, and weaker in Iodine, are offered, from the use of which the same therapeutic effects cannot be obtained.

Caution.—Use no Syrup of Hydriodic Acid which has turned red. This shows decomposition and free Iodine. In this state it acts as an irritant and fails to produce desirable results.

Unprincipled apothecaries substitute imitations when Gardner's Syrup is prescribed, and physicians, failing to get desirable and promised results, attribute the fault, unjustly, to Gardner's Syrup.

THERAPEUTIC INDICATIONS.

Hay Fever; Rose Cold; Poisoning by Lead, Mercury or Arsenic; Acute and Chronic Rheumatism; Asthma; Chronic Bronchitis; Catarrh; Congestion of Lungs in Children; Adenitis; Eczema; Lupus; Chronic Malarial Poisoning; Lumbago; Acute Pneumonia; Psoriasis; Scrofulous Diseases; Goitre; Enlarged Glands; Cold Abscesses; Indolent Sores; Excessive Fat; Fatty Degeneration of the Heart; to absorb non-malignant Tumors; and in the latter stages of Syphilis; Syphilitic Phthisis.

Details of treatment furnished physicians upon application to undersigned without charge.

Gardner's Chemically Pure Syrups of Hypophosphites.

Embracing the separate Syrups of Lime, of Soda, of Iron, of Potassa, of Manganese, and an Elixir of the Quinia Salt; enabling physicians to accurately follow Dr. Churchill's method, by which thousands of authenticated cases of Phthisis have been cured. The only salts, however, used by Churchill in Phthisis are those of Lime, of Soda, and of Quinia, and always separately according to indications,—never combined.

The reason for the use of single Salts is because of antagonistic action of the different bases, injurious and pathological action of Iron, Potassa, Manganese, etc., in this disease.
